THERE have been a few years that were epochal in the history of the treatment of syphilis 1905, with the discovery of the spirochete, 1906 with the development of the Wassermann reaction as a practical test for syphilis, 1910, with the success of Ehrlich's six hundred and sixtieth experiment, and a few others With these exceptions, the progress in any one year has not seemed consequential, but our small advances have been cumulative and over a period of years they show a long step forward as C Morton Smith¹ makes clear in his review of the changes in the treatment of syphilis during the last twenty years He traces our gain in the relief and control of this disease and in our efforts to educate the public in its attitude toward the syphilitic One proof of our success in the latter respect is evidenced by the fact that the past year in Boston saw what an officer of the Massachusetts Society for Social Hygiene² hailed as "the most recent single event of importance in the field of social hygiene" It was the production of the picture "Damaged Lives" which played to crowded houses Equally gratifying was the fact that Boston dramatic critics dared to refer to the keynote of the play, gonorrhea and syphilis, by name without resorting to euphemisms In this same city Nelson of the State Department of Public Health³ has been giving radio broadcasts on syphilis and gonorrhea with, it is said, not a single complaint against their frankness but a number of favorable comments and requests for further information At least one newspaper printed an editorial commending the talks

However, there still remains much educational work to be done when a court⁴ will annul a marriage because a woman having had ad-

vanced syphilis before marriage did not disclose the information to her husband With the same lack of understanding the appellate court, Louisiana,⁵ has ruled that an insurance policy which excludes from its coverage venereal diseases imposes no obligation on the insurer to compensate for the effects of syphilis, even though in recently acquired

If we are to prevent blindness from interstitial keratitis and the mental and physical defects of congenital syphilis, the medical public must be educated to greater vigilance in the care of the pregnant mother Lees⁶ reports that in Edinburgh among 1000 untreated pregnancies only 24.5 per cent of the children were sufficiently healthy to survive while a similar survey of efficiently treated mothers showed 89.2 per cent of healthy children, and an even larger percentage, if the treatment of the mother was begun before the sixth month of pregnancy At the Memphis General Hospital⁷ 1000 cases of syphilis in pregnant women were discovered over a period of ten years Of those receiving treatment, 65 per cent had normal, full-term babies with no evidence of syphilis Of those receiving no treatment, none had a normal, full-term infant with no serological or clinical evidence In view of these reports it is encouraging to know that the American Medical Association at its annual meeting in 1933 adopted a resolution⁸ requesting the House of Delegates to appoint a committee to arrange methods by which cooperation might be secured with the American Medical Association, the National Society for Prevention of Blindness, the American Social Hygiene Association, the obstetric and ophthalmologic societies, the American Dermatological Association, and public health organizations and such others as can help, to see that blood examinations are made of all pregnant women so that all cases of syphilis may be treated

*Cheever Austin W—Assistant in Dermatology and Syphilology Harvard University For record and address of author see This Week's Issue page 1083

The use of artificially produced heat in the treatment of central nervous system syphilis and the favorable results from malaria have stimulated many investigators to try to devise less dangerous and more controllable methods of producing fever. M. O. Nelson⁹ recommends combined typhoid vaccine which he found brought improvement in patients with resistant neurosyphilis. Epstein and Paul¹⁰ for two years have been using a diathermy apparatus capable of raising the body temperature to 41.1° (106° F). They describe their technic and results on a group of twenty-eight patients with various forms of central nervous system syphilis. Clinical improvement was noted in patients with all types of the disease but especially so in those with tabes dorsalis. One fatality occurred in a patient of advanced age with marked mental deterioration. Graham¹¹ obtained results better than those from malaria, he thinks, in twenty-four cases treated by diathermy though he records one death due to respiratory failure attributable to treatment. Worthing¹² describes a diathermy machine in which so far only a small number of patients have been treated. His results agree in general with those of other workers, but the author emphasizes the extreme discomfort of the patient after the temperature rises above 102 degrees.

Freeman, Fong, and Rosenberg¹³, on the other hand, found the substitution of diathermy for malaria in the treatment of dementia paralytica far from promising. They feel that early reports on the use of mechanical measures for producing fever have been premature. O'Leary¹⁴, too, feels that the results from malaria are still superior to those obtained from electrical machines. He has observed over a period of eight years almost one thousand patients with neurosyphilis who were treated with malaria and he has found that in more than three-fourths of the cases of asymptomatic dementia paralytica, clinical progress of the disease was arrested, and the serologic tests of the spinal fluid became reversed to complete negativity in almost half the cases of asymptomatic neurosyphilis in which routine measures of treatment had previously failed to influence the serology. The results in the treatment of tabes dorsalis and of the tabetic form of dementia paralytica were likewise encouraging.

In 1932 Gennerich¹⁵ reported on a new mercury preparation which he found intensely effective for all stages of syphilis but less active than arsphenamine. This year Lawless¹⁶ reports on this drug colloidal mercuric sulphide. He found it painless with no palpable infiltration and decidedly effective though too slow to be of use in the infectious stages of syphilis. It is highly recommended as a supportive drug with the arsphenamines and bismuth. A serious drawback is its rather constant resistant staining of the skin at the site of injection.

Because of inconclusive clinical results with 50 per cent mild mercurous chloride inunctions, Cole et al¹⁷ made a study of the mercury excretions in order to obtain a better criterion of its true absorption from the skin. They found it very poorly absorbed.

After a study of the different types of bismuth preparations—watery solutions, a solution in ethylene glycol, oily solutions and oil suspensions, Sollmann, Cole, and Henderson¹⁸ decided that the total dosage is much more important than the particular preparation used. They were impressed by the similarity in the absorption and excretion rate of all these compounds except the oil suspension of bismuth salicylate which showed much slower absorption and excretion. Distinct doubt is thrown upon the desirability of too rapid absorption in bismuth because of a correspondingly rapid excretion rate and the accompanying tendency to overburden the kidneys and liver. After studying five typical bismuth preparations as to rate of absorption, distribution in kidneys and liver, urinary excretion, irritation at site of injection, and toxicity, Thompson et al¹⁹ show that it is not yet established that a rapid absorption rate will result in a more effective concentration against syphilis. They confirmed the intimate relationship between absorption rate and toxicity, the preparations showing fastest absorption being most toxic.

An excellent summary of our knowledge of bismuth at the present time is found in a discussion of bismuth compounds by Irgang, Alexander, and Sala²⁰.

Bismuth has been recommended as a prophylactic against syphilis and in this connection it is interesting to see the report by Zetterholm²¹ of a reinfection in a patient during the course of continuous bismuth treatment. The same situation holds for stovarsol by mouth which has been recommended as a prophylactic. Tzanck et al²² report an instance of a patient's developing syphilis while taking stovarsol by mouth for non-syphilitic lesions.

After studying the effects of arsphenamine and tryparsamide in systemic syphilis and neurosyphilis in sodoku and in malaria, Solomon, Epstein and Berk²³ conclude that the value of the former drug is in its spirocheticidal and plasmodicidal effect as indicated by its action in stopping fever in malaria and in clearing the blood of plasmodia in inoculation malaria, while tryparsamide showed no effect on either fever or blood. However, this latter drug shows a power to stimulate tissue to rapid repair, a local action within the local areas of the nervous system.

Raiziss and Severac²⁴ made a very careful comparison of bismarsen and arsphenamine in rabbit syphilis. They conclude that bismarsen is as effective as arsphenamine in experimental syphilis in rabbits.

A comparative study of the results and reactions of neoarsphenamine and arsphenamine was made by Thornley²⁵. Taking a group of 999 patients who had been under observation or treatment for six months or longer, he found the difference in efficacy between the two drugs not very great when the neoarsphenamine is given well diluted, but when for greater convenience it is given in concentration, the reactions are much more numerous than with arsphenamine. To lessen the chances of treating syphilis with a brand of neoarsphenamine below the average in curative activity, since the different brands vary in anti-syphilitic properties, Schamberg and Kolmer²⁶ urge that the National Institute of Health establish official standards of therapeutic efficiency for this drug in addition to their present tests for toxicity.

A method of treatment worthy of further study is the work being done by Wittenberg²⁷ on a plan to introduce larger amounts of the arsphenamines into the central nervous system. His idea is to use drugs of the epinephrine group to cause cerebral vasodilation, followed in two minutes, the time of the height of the dilation, by neoarsphenamine.

A distinct inhibitory effect on syphilis in rabbits through the use of trypan blue has been found by Morgan et al²⁸. They suggest that it is produced not by spirocheticidal action but by the increase of the number and activity of the phagocytic mononuclear cells.

Robinson²⁹ discusses a case of "fixed" dermatitis in a patient having tryparsamide showing a striking resemblance to that caused by phenolphthalein. The eruption could be brought out at will by giving injections of tryparsamide.

Serefis³⁰ believes that salvarsan intolerance can be prevented or cured by decreasing the sodium chloride content of the food and increasing its content of potassium, calcium, and magnesium.

Belding and Arrowood³¹ made a quantitative study of three flocculation tests, Sigma, Kahn, and Hinton, from the standpoint of sensitivity and variability. They found the Hinton test the most sensitive in detecting syphilitic reagin, the Kahn next, and the Sigma the least. The Hinton showed less variability, they report, than the other two. These investigators³² in making preliminary experiments to determine the suitability of the Hinton test for laboratory routine found what they consider possibilities for adapting this test for quantitative work. They described the technical considerations involved in such a modification.

Dental observations are being made on syphilitic teeth by induced electric currents. So far only a preliminary report³³ has been made of abnormalities which seem to be connected with syphilis.

Wile³⁴ has made a very careful analysis of a

group of 157 cases of syphilis with cardiovascular involvement occurring preponderantly in males averaging from 46 to 53 years in age, the milder involvement being at the later age. The average duration of the disease before clinical detection varied from 15 years in the severe cases to 24 in the mild. A moderate number of the group had had some previous antisyphilitic treatment, but practically none had had what would now be called satisfactory.

The pathology, clinical features, and treatment of cardiovascular syphilis have been most ably presented by Mallory, White, and Smith³⁵ and should be read in their entirety by those interested in the problem.

After examining 1,548 patients with cancer of the mouth at the Collis P. Huntington Memorial Hospital, Lund³⁶ found that 122 had syphilis, also. Of 401 patients with cancer of the tongue, 70 had syphilis. Lund calls syphilis a contributing cause of cancer of the tongue. In the experience of Molesworth³⁷, who reported last year on this subject, 20 to 30 per cent of cancers in the mouth occurred in persons showing positive serology.

In the opinion of Wheeler³⁸ a persistently positive serum reaction means uncured syphilis. He arrived at this conclusion after a study of 200 patients with persistently positive serology.

Herrmann³⁹ feels that syphilitic disease of the peripheral arteries is not an uncommon occurrence. He describes three types: the angiospastic, occurring in upper extremities and manifesting itself as a chronic arteriospasm, the endarteritic, seen in the legs and feet with constant pain, the thromboarteritic, uncommon, manifesting itself by extensive organic occlusion of all the major pathways of the extremities without evidence of gross gangrene. Active antisyphilitic treatment should be the first step in the management of these disturbances. Treatment by means of an intermittent negative pressure environment is the most effective in the opinion of the author.

At an Illinois State Institution⁴⁰ where up to 1930 there was no routine antisyphilitic treatment, records of all patients up to that time were carefully examined, and of the 59 found to have positive reactions on admission, eighteen (30.5 per cent) of varying ages and length of stay now have negative tests although they have received no antisyphilitic treatment.

It is not yet sufficiently realized that intra-urethral chancres occur more frequently than is generally supposed. Strachstein⁴¹ reports six cases and calls attention to the fact that a persistent so-called simple urethritis may indicate a probable intraurethral chancre. Serra⁴² reviews the cases of extragenital primaries seen at the dermatosyphilitic clinic of Turin from 1889-1931. Nine and two tenths per cent of the total number of cases showed extragenital lesions. Cases of extragenital syphilitic infec-

tions in six female members of one family transmitted through the common use of eating utensils is reported by Jeno Follman⁴²

It is not possible to overemphasize the importance of care in choosing transfusion donors. A secondary rash developed in a girl fourteen years of age after she had received blood from her brother, whose chancre appeared four or five days later⁴⁴

For years it has been a controversial point as to whether there are other forms of the organisms of syphilis than the familiar *Spirocheta pallida*. Numerous facts can be satisfactorily explained on the ground of a life cycle such as is known in some other organisms. Levaditi and others⁴⁵ working at the Pasteur Institute in Paris are studying this problem. They feel that it is probable that the virus undergoes certain phases in its evolutionary cycle before it can invade the central nervous system and that it then passes through alternating phases in the nervous system, sometimes invisible sometimes in the form of spirochetes and that this explains the inconstancy of the findings in the cortex of general paralytics. Coutts⁴⁶ believes that certain cases of syphilitic infection with no apparent infective lesions can be explained by the possibility that latent syphilitics may become active carriers of *Spirocheta pallida*. He cites two cases where this seems the only satisfactory explanation as to the mode of contagion.

If we are to gain complete control of syphilis, sources of infection and exposures must be traced. Smith and Brumfield⁴⁷ by the careful questioning of 119 patients with rather recent syphilis discovered and placed under treatment 93 syphilitic contacts. From one original case 19 contacts were traced, having either primary or secondary syphilis or positive blood tests. Nelson of the Massachusetts State Department of Public Health⁴⁸ feels that much will be accomplished when the physician in his office practice uses the same careful follow-up that is used in the best clinics. He describes an experimental service which the State has offered a few physicians treating syphilis and gonorrhea where by a trained investigator or social worker is sent out by the State Department to work with the doctor on lapsed cases. Though the results were sufficient to demonstrate the value of such service, it has not yet been possible to "sell" this service to the majority of physicians.

A study of field work over a period of nine months in the clinics and activities of seven institutions has been made by Morris⁴⁹. The author summarizes her findings and makes general recommendations. Her report is of interest to institutional workers.

Two valuable books have added to the year's progress. The History and Epidemiology of Syphilis by William Allen Pusey⁵⁰ presents in an unusually attractive form the three Gehr-

mann lectures delivered by the author at the University of Illinois on the historical and epidemiological aspects of syphilis. Joseph Earle Moore⁵¹ in the Modern Treatment of Syphilis has given us a monograph of over five hundred pages generously supplied with references to the best literature on the subject. By the very free use of graphs and tables and by employing the simplest language possible, this book makes readily available information as to what can be done for patients with various types of syphilis and what results may be expected from the treatment.

MORTALITY RATES

Telegraphic returns from 86 cities, with a total population of thirty seven millions for the week ending April 28, indicate a mortality rate of 120 as against a rate of 113 for the corresponding week last year. The highest rate (184) appears for Washington, D. C., and the lowest (68) for Evansville, Ind., and Long Beach, Calif. The highest infant mortality rate (164) appears for San Antonio, Texas, and the lowest for Albany, N. Y., Fort Wayne, Ind., Long Beach, Calif., New Haven, Conn., Omaha, Neb., Somerville, Mass., South Bend, Ind., Spokane, Wash., Syracuse, N. Y., Tampa, Fla., Utica, N. Y., Waterbury, Conn., and Youngstown, Ohio, which reported no infant mortality.

The annual rate for 86 cities is 126 for the seventeen weeks of 1934 as against a rate of 120 for the corresponding period of the previous year.

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS)
FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED
POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS
OF 1934 AND 1933

	Week ending		First 17 weeks	
	April 28, 1934	April 29, 1933	1934	1933
Total deaths	134	113	2,660	2,344
Death rate	187	157	218	192
Deaths due to accidents in city	104	90	2,170	1,892
Death rate	145	125	178	155

MR STRAWSON RESIGNS

After fifteen years with the National Tuberculosis Association, Arthur J. Strawson has resigned to accept the position of executive secretary of the Southern Worcester County Health Association, 5 Pleasant Street, Worcester, Massachusetts. He will assume his new office on June 4.

Upon graduating from Northwestern University in 1908, Mr. Strawson was with *The Survey* and in settlement work for three years and then spent four years with the Chicago Tuberculosis Institute and the Illinois Tuberculosis Association. He left Chicago to become executive secretary of the Indiana Tuberculosis Association resigning from this position for work with the American Red Cross during the World War. He served in camps for the Red Cross in Kentucky and Indiana and later was a field agent for National Headquarters. In 1919 he became regional secretary for the National Tuberculosis Association in the North Mississippi Valley with headquarters in Indianapolis. When the regional offices were discontinued in 1920, he came to New York as field secretary.

Mr. Strawson's countrywide experience has familiarized him with all phases of the program for tuberculosis control. The staff of the National Association feel profound regret at his resignation but congratulate Worcester County on securing his valuable services and rejoice that he is to continue in the tuberculosis field.—*Bulletin of the National Tuberculosis Association*

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL PATHOLOGIC EXERCISES

EDITED BY RICHARD C CABOT, M.D.
F M PAINTER, A.B., ASSISTANT EDITOR

CASE 20201

PRESENTATION OF CASE

The patient, a fifty-eight year old Irish cook, was perfectly well until one week before entry, at which time she began to have loss of appetite. Five days before entry she had a rather severe upper abdominal pain which radiated through the body to both shoulder blades. Aspirin did not give relief. She began to vomit immediately after eating, despite the fact that she had been taking only soft solid foods. Two or three days before admission the pain became less severe, but the vomiting persisted and at this time there was coffee grounds vomitus. This condition persisted until admission and produced increasing weakness.

Physical examination showed an obese middle-aged woman mentally alert and talkative. She did not appear ill except for a sallow complexion and the fact that she was vomiting coffee grounds material without much nausea or retching. The sclerae were muddy but not definitely icteric. The heart was moderately enlarged. The aortic second sound was loud. There was a systolic blowing murmur at the apex and the base. The blood pressure was 280/135. The abdomen was soft and not tender. The examination was brief because manipulation brought on further hematemesis. No organs or masses were noted.

Examination of the urine showed a yellow test for sugar and a positive acetone. There was no albumin. The blood sugar was 312 milligrams. The carbon dioxide combining power was 51+ volumes per cent. Examination of the blood showed a red cell count of 5 000 000, 75 per cent hemoglobin and a white cell count of 17 000.

The temperature was 96.4°, the pulse 160, the respiratory rate 25.

In the Emergency Ward she was immediately given intravenous glucose five per cent, followed by thirty units of insulin. When she arrived in the medical ward she went into further collapse. The temperature was 100°, the pulse 160 and the respiration 45. The blood pressure was 100/70. She was cold and sweating. A clviss of 2½ per cent glucose was given, and 500 cubic centimeters of citrated blood by transfusion. The patient felt somewhat better and stopped vomiting. The pulse fell to 130 and the blood pressure rose to 130/70. This improved

condition lasted until seven o'clock the following morning. At that time her blood pressure fell to 60-70 systolic and the pulse became too feeble to count. A second transfusion of 500 cubic centimeters of citrated blood was given. That afternoon she vomited two more kidney basinfuls of coffee grounds material. The blood sugar was down to 114 milligrams. The carbon dioxide combining power was 50.7 volumes per cent. Her abdomen became fuller and more tense but no free fluid was demonstrated. There was a diffuse tenderness all over the abdomen, with some spasm. She rapidly failed and died that day.

DIFFERENTIAL DIAGNOSIS

DR OLIVER COPE. The essentials seem to me to be that this patient is a woman of fifty-eight years who, following a period of at least a week's duration of loss of appetite and vomiting, was found to have hypertension and was incriminated with diabetes.

The past history is lacking.

The essentials of the physical examination at the time of her entry are unavoidably casual because of the fact that the vomiting increased as a result of any manipulation.

In looking at the subsequent history the diabetes seems to me to be distinctly incidental, although apparently she was treated with that seriously in mind. I believe it was the kind of diabetes that might occur in a patient of her age with arteriosclerosis and a mild tendency to diabetes aggravated by starvation and vomiting. I therefore would rule out the diabetes and I would think of those things that might have increased her blood sugar level and caused the excretion of sugar in her urine. The first thing I think of is of course an infection, and I would rule out rarer things like bronzed diabetes. I do not think that a sallow complexion and muddy sclerae are enough to incriminate her in that regard.

When we consider her subsequent course during the hospital stay—first of all she was very talkative and alert, and then went into rapid collapse following only a week's history—I should think of peritonitis in spite of the fact that we are told that her abdomen showed no tenderness and no masses. Her symptoms are certainly consistent with peritonitis. They are, however, no more specific than upper abdominal discomfort and pain between both shoulder blades. Peritonitis in a woman of her age might arise from many different sources. The thing that one would want to know is what one could feel in her abdomen at the time one saw her. They felt nothing therefore it comes down to probabilities. I should like to commit myself and say that the most probable thing is an acute appendicitis which ruptured. The picture fits into that diagnosis. She had loss of appetite for two days and then sudden onset of pain and vomiting.

I omitted to speak of the coffee grounds material. There is no mention that that was actual blood. If so it would make one think of malignancy. It does not seem to me to fit into the picture of bleeding ulcer or of an uncomplicated intestinal obstruction. You could possibly get blood under the latter circumstance. I am still inclined, even though there was a positive guaiac, to say definitely that it was peritonitis. I am probably wrong, but I do not see any other way out.

As the cause of peritonitis the probability even at her age would be in favor of appendicitis. Also, since her symptoms were upper abdominal, in the examination of the abdomen it would be likely that the attention was paid during the cursory examination to the upper abdomen and that tenderness somewhere in the lower abdomen might have been overlooked. I think I must ascribe the symptoms to appendicitis in the absence of any earlier past history. I think it is peritonitis probably originating in a ruptured appendix.

CLINICAL DISCUSSION

DR TRACY B MALLORY. We have here an obviously very blind case in which many guesses would be possible. I wonder if anyone else would like to make a diagnosis.

DR E PARKER. I think it quite possible she had carcinoma of the stomach with perforation. This complication occurs now and then, and would explain the peritonitis and also the blood in the vomitus.

DR GEORGE A LELAND, JR. It appears from the record that on the morning after her admission I saw this patient in consultation and stated that I was unable to make a diagnosis but that I felt very certain that in her condition at that time exploratory laparotomy would be of no avail. I vaguely remember the case. At that moment she was perfectly pulseless, with cold extremities. Effort was being made to build her up with some fluids. That was less than six hours before she died.

In retrospect, and considering the history as given today, I am inclined to agree with Dr Cope that the hypertension and the diabetic condition are merely an unfortunate background of the individual and merely contributive rather than responsible for the very rapid dissolution that she underwent. As to what the acute condition was I am still very much in a quandary. With a patient of fifty-eight one thinks very seriously of malignancy of course. This woman had a red cell count of 5,000,000 and a hemoglobin of 75 per cent, which is fairly high for a malignancy of any long standing. On the other hand this blood picture is consistent with a cancer of non-ulcerated type without bleeding. The hematemesis is I think of course very significant in this case. I do not think we can pass it over lightly. I believe that the patient

had a malignancy which involved her stomach, either primarily as cancer of the stomach with acute massive hemorrhage, or else an extrinsic cancer perhaps originating from the large bowel or the adjacent pancreas which ulcerated through into the stomach. I believe that the primary cause of death was an acute emergency due to a cancer.

DR WILLIAM B BREED. One might guess pancreatitis as tying two of the conditions together, namely the appearance of peritonitis and the disturbance in the sugar metabolism. I am not sure that the hematemesis could be explained on the basis of pancreatitis, but one does see occasionally hematemesis with pancreatitis.

DR MALLORY. We certainly have seen cases of pancreatitis in which there has been a considerable elevation in blood sugar and the sudden appearance of sugar in the urine.

DR J H MEANS. I think that with the coffee grounds vomitus the chances of cancer are very great.

CLINICAL DIAGNOSES

Peritonitis, cause unknown
Intestinal obstruction
Diabetes mellitus

ANATOMIC DIAGNOSES

Thrombosis of the superior mesenteric, portal, splenic and pancreatic veins
Gangrene of the intestines
Generalized peritonitis
Ulcer of the esophagus with perforation into the posterior mediastinum and both pleural cavities
Partial obstruction of the inferior vena cava by a sclerosed thrombus with collateral circulation through the left ovarian vein
Chronic fibrous pleuritis
Arteriosclerosis, marked aortic, slight coronary and renal

PATHOLOGIC DISCUSSION

DR MALLORY. After having seen the autopsy on this case one can go back to one point in the story which I think one otherwise would overlook entirely, and that was that her presenting symptom had been pain between the two shoulder blades. She had two lesions which I am unable to connect directly. One, which I think probably explains that pain in the back and also explains the coffee grounds vomitus, was an ulcer of the esophagus which perforated into both pleural cavities. There was about 700 cubic centimeters of coffee grounds stomach material in the right pleural cavity and about 400 cubic centimeters of the same material in the left pleural cavity. The communication between the two pleural cavities was evidently digested by the gastric juice. That however

was not the cause of her death. In addition to that she had developed an acute mesenteric thrombosis starting in the superior mesenteric vein, running up the portal vein and involving the splenic vein. The small intestine from about one foot beyond the duodenum down nearly to the terminal ileum was completely gangrenous and secondary to that arose the peritonitis which had been suspected. A further finding—probably a historical landmark only—was an old thrombotic occlusion of the inferior vena cava, with a well-developed collateral circulation through a greatly dilated left ovarian vein.

A PHYSICIAN. Did that ulcer of the esophagus show any gastric tissue?

DR MALLORY. The postmortem digestion was so great that we were unable to recognize anything in its wall. I am quite sure it was not neoplastic. I think enough tissue was present for it to have been recognized if it had been.

DR FULLER ALBRIGHT. Did she have a high temperature before she died?

DR MALLORY. There was a terminal temperature of 105°.

DR ALBRIGHT. I saw a case in Vienna something like this one. Professor Eidheim explained it in the following way. If a person for several days before death is extremely sick so that tissue resistance is decreased and if he at the same time has a high temperature the gastric juice may run back into the esophagus and digest an opening through this organ. The gastric juice then flows down into the pleural cavity. The condition is most often seen in cerebral cases because of their tendency to develop hyperpyrexia.

DR MALLORY. Although in this case we have a history of pain high in the back, suggesting that this is an earlier lesion.

DR EDWARD L. YOUNG, JR. We see the same thing in cases of lateral sinus thrombosis with tremendous elevation in temperature in the last few hours.

CASE 20202

PRESENTATION OF CASE

First admission. The patient, a sixty-six year old Canadian laundress had been in good health until one year before admission. At that time she began to have a severe diarrhea. The discharge consisted of mucus, blood and thin watery feces. At times she was almost incontinent. This diarrhea continued, and was often associated with a sensation of fullness in the rectum. She had no other symptoms and had been working until two weeks before admission. There had been no jaundice, weakness, abdominal pain or night sweats. She had lost twenty pounds in the past three months.

Twenty-seven years before admission she had pleurisy which necessitated a three months' stay at a hospital. She was discharged feeling well,

but every winter since then had developed a cough associated with white sputum, occasionally blood streaked. During that year she fractured several ribs in an accident. For the past five years she had had dyspnea on climbing stairs. She had no edema. Three years before admission both knees became painful and swollen. A physician made a diagnosis of rheumatism. Two years before admission she fell down stairs and refractured two ribs. There was no history of pneumonia, chorea, or association with tuberculosis.

Physical examination showed the left pupil to be greater than the right. It did not react to light and was slightly irregular. The chest was slightly barrel shaped. The heart was enlarged to the left. There was a precordial systolic murmur, loudest at the aortic area. The aortic second sound was booming and greater than the pulmonary second. The blood pressure was 190/90. The abdomen was soft and slightly tender in the lower portion. No masses were felt. Rectal examination showed several large external hemorrhoids. Eight centimeters above the anus was a cauliflower polypoid mass which occupied the right half of the rectal wall. It was about 5 centimeters in diameter bled easily, but did not completely obstruct the lumen. The knee jerks and ankle jerks were absent.

Examination of the urine was negative. The blood showed a red cell count of 4,500,000, a hemoglobin of 90 per cent and a white cell count of 5,500. A Hinton test was negative. The non-protein nitrogen of the blood was 25 milligrams. A phenolsulphonephthalein test showed 60 per cent excretion at the end of two hours.

An electrocardiogram showed normal rhythm, rate 70 and left axis deviation. A lumbar puncture was negative.

X-ray examination of the chest showed enlargement of the heart. The transverse diameter was 13.8 centimeters and that of the chest 23.8 centimeters.

Six days after admission a first stage abdominal perineal excision of carcinoma of the rectum was performed. The postoperative course was stormy. She developed pulmonary collapse and some pneumonia. On the seventeenth day after operation a second stage resection of carcinoma of the rectum was performed. Following this she was given a transfusion of 400 cubic centimeters of whole blood. This time she did well postoperatively. On the thirty-third day after the first operation she was discharged to a convalescent home.

Second admission. Two months after her previous discharge.

She entered this time because of a fecal fistula in the posterior wound of the old abdominal perineal resection. The colostomy had nearly fallen back into the abdomen. The opening was very small. A plastic to the colostomy was performed under local anesthesia. She was dis-

I omitted to speak of the coffee grounds material. There is no mention that that was actual blood. If so it would make one think of malignancy. It does not seem to me to fit into the picture of bleeding ulcer or of an uncomplicated intestinal obstruction. You could possibly get blood under the latter circumstance. I am still inclined, even though there was a positive guaiac, to say definitely that it was peritonitis. I am probably wrong, but I do not see any other way out.

As the cause of peritonitis the probability even at her age would be in favor of appendicitis. Also, since her symptoms were upper abdominal, in the examination of the abdomen it would be likely that the attention was paid during the cursory examination to the upper abdomen and that tenderness somewhere in the lower abdomen might have been overlooked. I think I must ascribe the symptoms to appendicitis in the absence of any earlier past history. I think it is peritonitis probably originating in a ruptured appendix.

CLINICAL DISCUSSION

DR TRACY B MALLORY: We have here an obviously very blind case in which many guesses would be possible. I wonder if anyone else would like to make a diagnosis.

DR E PARKER: I think it quite possible she had carcinoma of the stomach with perforation. This complication occurs now and then, and would explain the peritonitis and also the blood in the vomitus.

DR GEORGE A LELAND, JR: It appears from the record that on the morning after her admission I saw this patient in consultation and stated that I was unable to make a diagnosis but that I felt very certain that in her condition at that time exploratory laparotomy would be of no avail. I vaguely remember the case. At that moment she was perfectly pulseless, with cold extremities. Effort was being made to build her up with some fluids. That was less than six hours before she died.

In retrospect, and considering the history as given today, I am inclined to agree with Dr Cope that the hypertension and the diabetic condition are merely an unfortunate background of the individual and merely contributive rather than responsible for the very rapid dissolution that she underwent. As to what the acute condition was I am still very much in a quandary. With a patient of fifty-eight one thinks very seriously of malignancy of course. This woman had a red cell count of 5,000,000 and a hemoglobin of 75 per cent, which is fairly high for a malignancy of any long standing. On the other hand this blood picture is consistent with a cancer of non-ulcerated type without bleeding. The hematemesis is I think of course very significant in this case. I do not think we can pass it over lightly. I believe that the patient

had a malignancy which involved her stomach, either primarily as cancer of the stomach with acute massive hemorrhage, or else an extrinsic cancer perhaps originating from the large bowel or the adjacent pancreas which ulcerated through into the stomach. I believe that the primary cause of death was an acute emergency due to a cancer.

DR WILLIAM B BREED: One might guess pancreatitis as tying two of the conditions together, namely the appearance of peritonitis and the disturbance in the sugar metabolism. I am not sure that the hematemesis could be explained on the basis of pancreatitis, but one does see occasionally hematemesis with pancreatitis.

DR MALLORY: We certainly have seen cases of pancreatitis in which there has been a considerable elevation in blood sugar and the sudden appearance of sugar in the urine.

DR J H MEANS: I think that with the coffee grounds vomitus the chances of cancer are very great.

CLINICAL DIAGNOSES

Peritonitis, cause unknown
Intestinal obstruction
Diabetes mellitus

ANATOMIC DIAGNOSES

Thrombosis of the superior mesenteric, portal, splenic and pancreatic veins
Gangrene of the intestines
Generalized peritonitis
Ulcer of the esophagus with perforation into the posterior mediastinum and both pleural cavities
Partial obstruction of the inferior vena cava by a sclerosed thrombus with collateral circulation through the left ovarian vein
Chronic fibrous pleuritis
Arteriosclerosis, marked aortic, slight coronary and renal

PATHOLOGIC DISCUSSION

DR MALLORY: After having seen the autopsy on this case one can go back to one point in the story which I think one otherwise would overlook entirely, and that was that her presenting symptom had been pain between the two shoulder blades. She had two lesions which I am unable to connect directly. One, which I think probably explains that pain in the back and also explains the coffee grounds vomitus, was an ulcer of the esophagus which perforated into both pleural cavities. There was about 700 cubic centimeters of coffee grounds stomach material in the right pleural cavity and about 400 cubic centimeters of the same material in the left pleural cavity. The communication between the two pleural cavities was evidently digested by the gastric juice. That however

taminating the peritoneal cavity. That procedure, in view of the twenty-four hours of obstructive symptoms, is somewhat questionable. I think it would have been distinctly better to drain the bowel at that time, particularly in view of the evacuation of some fifty ounces of fluid a few hours later. There would be no more risk in putting a tube in at operation. That is the procedure that is usually carried out.

After the evacuation of fifty ounces of fluid the drainage stopped, the patient began to get worse, and then a period of thirty-six hours elapsed during which there was gradually progressive distention and no drainage. On the face of it I should say that there was probably an obstructing point somewhere in the small bowel above. It may have been that the patient was developing peritonitis without any particular evidence of spasm, but it seems to me more likely that there was intestinal obstruction higher up. Knowing the type of operation that was probably done, a very likely situation is that the small intestine may have rotated from right to left around the colostomy and formed a condition which, although it might not obstruct all the time, at the same time was a definite factor in the obstruction. That sort of thing occurs with reasonable frequency in what essentially amounts to an intra-abdominal hernia around the left side of the colostomy with interference in circulation due to the drag on the mesentery. This may have been the situation. I should think from the history that it would probably have been wise to have gone in rather promptly after the drainage stopped and the distention increased and that under novocain anesthesia one could have put a catheter in a loop of distended ileum somewhere.

DR ROBERT R. LINTON: I saw this patient when she came into the Emergency Ward the last time. The picture at that time was certainly one of intestinal obstruction, most probably of the small bowel, and that was why operation was advised. Dr. Stewart, who did the operation, reported that the small bowel was somewhat dilated, but not so much as the cecum. The cecum was so tense and dilated that it was impossible to get a tube into it, so he thought it was much safer to suture it to the peritoneal surface and open it later. The colostomy was irrigated before operation, with practically no return. It seemed pretty definite that she had mechanical obstruction.

A PHYSICIAN: Would the dilated cecum more or less rule out a point of obstruction above it?

DR HAYDEN: It would, unless a small intestinal obstruction occurred a little later, when the free flow from the cecostomy stopped. There was no reason why any quantity of material

would collect in the cecum unless there was obstruction below it.

CLINICAL DIAGNOSES

Acute intestinal obstruction
Carcinoma of the rectum

ANATOMIC DIAGNOSES

Mesenteric thrombosis (embolism?)
Operative wounds: old resection of anus, rectum and sigmoid (cancer of rectum), recent cecostomy
Peritonitis: slight, generalized
Arteriosclerosis: marked aortic, moderate coronary, mesenteric and renal
Cardiac infarct, old
Mural thrombi, left ventricle and aorta
Healed pulmonary tuberculosis, left
Chronic fibrous pleuritis, bilateral
Cervical polyps

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: The obstruction, if one is to call it obstruction in this case, was similar to that in the last. It consisted in an infarction of the entire intestinal tract, in this case from the duodenum not merely down to the terminal ileum but also including the major part of the large intestine. Whereas in the last case the infarction was of venous origin from a thrombosis to the branches of the portal vein, in this case it was of arterial origin from occlusion of the mesenteric artery. The occlusion may have been a local thrombotic affair, since a fairly marked degree of arteriosclerosis was present in the mesenteric artery itself and numerous atheromatous ulcerations were formed in the aorta. Or it is possible that it may have originated in an embolus, for which she had a perfectly good focus in an infarct of the heart with an overlying mural thrombus. From this a clot might well have slipped off and become the starting point for the gradually progressive thrombosis of the mesenteric artery. The coronary arteries were free from occlusion. This infarct was a very old one. I think we must assume that she had at one time a coronary occlusion followed by almost complete recanalization of the artery.

A SURGEON: There were no metastases?

DR MALLORY: No.

DR HOLMES: Was there anything to account for the unusual position of the esophagus?

DR MALLORY: We did not notice anything.

The third case of this group, in which much of the general discussion of the group appears, will be published next week.

charged improved two weeks after admission. The colostomy was working well.

History of interval Three days after her discharge she began to have upper abdominal cramps which continued every few minutes through the whole day and evening. Soon after the onset of the pain she vomited. She vomited several times after this, at first food, then a small amount of blood and blood clot, and finally material which was fecal in character. Her colostomy was discharging feces at the time of entry.

Third admission, four days after her discharge.

Physical examination was similar to that at the second entry except that the heart impulse was felt 12 centimeters to the left of the mid-sternal line in the fifth interspace. The pulse was rapid, 110. The blood pressure was 125/100. The abdomen was moderately distended, with active peristalsis. It was soft and not spastic.

Examination of the blood showed a white cell count of 12,000. The non protein nitrogen was 52 milligrams. The carbon dioxide combining power was 33.9 volumes per cent. The serum protein was 3.9 per cent.

On the day of admission an extraperitonealization of the cecum was performed under local anesthesia. The dilated cecum was sewed to the peritoneal surface and a right lateral lower quadrant wound packed open. Three hours later a tube was sewed into the cecum and placed on six centimeters water suction. Over fifty ounces of fluid feces was evacuated. The cecostomy failed to drain for the next thirty-six hours. There was increasing abdominal distention. The temperature and pulse rose to 104° and 140 respectively. Two days after admission the patient died.

X-RAY INTERPRETATION

DR GEORGE W HOLMES. These films were taken four months before death and may have no bearing on the immediate trouble.

The films taken of the abdomen show shadows which could be either in the kidney or the gall bladder, but which have the characteristic appearance of gall stones. We can be fairly certain that she had gall stones from this film alone.

In the film of her chest, also taken four months before death, the most striking thing is the marked increase in the supracardiac shadow, probably due to tortuosity of the aorta and not to actual dilatation. Here we have a very good chance to measure the diameter of the aorta between the esophagus and the outer side of the shoulder. I think that is slightly increased, but not more than one would expect at her age. The increase is not great. The curve of the left ventricle is a little prominent. One would interpret these findings as being due to arteriosclerosis with some hypertension, with possibly some dilatation of the aorta.

The position that the esophagus takes is also interesting. It seems to lie very close to the descending aorta. We have seen a few cases of this type, and we have been wondering whether there were adhesions or some abnormality of the mediastinum that fixed the esophagus to the aorta.

This is the oblique view and shows the aorta very well. This is the lower end of the esophagus in its normal position.

DIFFERENTIAL DIAGNOSIS

DR E PARKER HAYDEN. This history is of course a very typical one of cancer of the rectum, confirmed by operation, so that the obscurity of diagnosis dates from the postoperative complications.

This woman was sixty-six years old, and had, I judge, a certain amount of cardiovascular disease, which probably had very little to do with her subsequent death. In view of Dr Holmes' x-ray interpretation, however, it may have had more to do with it than I think it did.

She had a two-stage operation of some type, probably the type which Dr D F Jones originated and which is ordinarily done in this hospital, in which a loop colostomy is done at the first stage with a pelvic dissection and the rectum is taken out later, leaving a blind loop of bowel which extends from the colostomy down to the upper part of the pelvis. The colostomy subsequently retracted. That is a pretty common thing, particularly in persons with a fat abdominal wall associated with a short mesentery and producing retraction of the posterior wall with a tendency for the colostomy stoma to contract. This may have resulted in a mild amount of intestinal obstruction prior to the plastic operation.

The plastic, I assume, was a simple novocain procedure, done without entering the peritoneal cavity. It gave the patient a chance to move her bowels and probably made her condition temporarily satisfactory.

She entered the hospital four days after discharge with typical symptoms, it seems to me, of intestinal obstruction. Her abdomen showed no spasticity but was moderately distended. Her white cell count was moderately elevated, to twelve thousand. Her temperature was up very slightly. I should say that the picture was fairly typical of intestinal obstruction.

An operation was done under novocain anesthesia, presumably because she was very sick and because the obstruction had been going on for twenty-four hours. The cecum was apparently sewed to the peritoneal wall bordering the incision. We must assume that the cecum was definitely distended and that the operator thought the obstruction to be somewhere below the cecum. Apparently he thought that by anchoring the cecum and allowing it to seal before he opened it he would run less chance of con-

taminating the peritoneal cavity That procedure, in view of the twenty-four hours of obstructive symptoms is somewhat questionable I think it would have been distinctly better to drain the bowel at that time, particularly in view of the evacuation of some fifty ounces of fluid a few hours later There would be no more risk in putting a tube in at operation That is the procedure that is usually carried out

After the evacuation of fifty ounces of fluid the drainage stopped, the patient began to get worse, and then a period of thirty six hours elapsed during which there was gradually progressive distention and no drainage On the face of it I should say that there was probably an obstructing point somewhere in the small bowel above It may have been that the patient was developing peritonitis without any particular evidence of spasm, but it seems to me more likely that there was intestinal obstruction higher up Knowing the type of operation that was probably done, a very likely situation is that the small intestine may have rotated from right to left around the colostomy and formed a condition which although it might not obstruct all the time, at the same time was a definite factor in the obstruction That sort of thing occurs with reasonable frequency in what essentially amounts to an intra-abdominal hernia around the left side of the colostomy with interference in circulation due to the drag on the mesentery This may have been the situation I should think from the history that it would probably have been wise to have gone in rather promptly after the drainage stopped and the distention increased, and that under novocain anesthesia one could have put a catheter in a loop of distended ileum somewhere

We must assume that the cecum was definitely distended and that the operator thought the obstruction to be somewhere below the cecum. Apparently he thought that by anchoring the cecum and allowing it to seal before he opened it he would run less chance of con-

although severe renal damage, particularly in the form of tubular nephritis, is also an important factor

The chief danger lies in the uncontrolled sale of this powerful agent to the laity. There is nothing that will prevent its use in the various patent medicines for reducing. There is nothing to prevent its over-the-counter sale by druggists. Potentially dangerous when prescribed by physicians to patients under strict supervision, it may be deadly to those taking it without competent advice. All too often the uninitiated and enthusiastic seeker of slimmness falls into the same difficulty as that met with by the lay user reported by the London correspondent in the *Journal of the American Medical Association*. Although the dose was stated to be one capsule a day she took seventeen capsules in a three-day period and died.

It is to be hoped that as wide publicity will be given to the dangers of this metabolism stimulating substance as has been given to its possible advantages.

THE TAX IMPOSED BY TUBERCULOSIS

The article by Dr C. E. A. Winslow on page 1084 of this issue presents in impressive form the tax levied on communities by tuberculosis. Unlike the increasing taxation of the federal and state governments, Dr Winslow shows that the burden of tuberculosis has been diminishing, and may be less if we continue to concentrate on the problems incident to this disease.

Until Koch's revelation of the pathology of the disease, little progress had been made in combating it. In the light of the discovery of the bacillus, physicians and public health authorities united in patient study of the possibilities of control, with the result that many thousands of lives have been saved and the great proportion of the tuberculosis tax has been lifted. Fortunately, Koch's discovery opened the fields of scientific research and led to other triumphs in dealing with disease which in turn diminish the burden of morbidity and mortality. It is well that due credit should be given to scientific medicine through its assistance in diminishing the taxable burden of disease.

Further progress will be made if and when more general knowledge permeates society at large followed by more generous cooperation with physicians and public health agencies.

TRIBUTE TO
DR WILLIAM HENRY WELCH

SUPPLEMENTING the editorial of last week and the letter by Dr Joseph H. Pratt, we are privileged to present three more references to Dr Welch which appear on pages 1087 to 1089.

Dr Welch visited Boston on many occasions and delivered several addresses here. His Ether Day Address at the Massachusetts General Hospital in 1908 and that on the importance of medical libraries in 1930 will be remembered by those privileged to hear them.

Those who were associated with or studied under him are unanimous in attributing to this eminent man great influence in the progress of medicine in this country.

His love for Johns Hopkins University School of Medicine is shown by the bequest of one-fourth of his estate, including his medical, scientific, and literary books, and medals to this organization.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

BOWLER, JOHN P. A.B., M.Sc., M.D. Harvard University Medical School 1919 F.A.C.S. Dean, Dartmouth Medical School Surgeon, Hitchcock Hospital, Hanover, New Hampshire. Address Hitchcock Clinic, Hanover, New Hampshire. Associated with him is GILE, JOHN F. A.B., M.D. Harvard University Medical School 1920 F.A.C.S. Instructor, Dartmouth Medical School. Surgeon, Hitchcock Hospital, Hanover, New Hampshire. Address Hitchcock Clinic, Hanover, New Hampshire. Their subject is "Compression Fractures of Vertebral Bodies." Page 1052.

MORSE, JOHN L. A.M., M.D. Harvard University Medical School 1891 F.A.A.P. Professor of Pediatrics Emeritus, Harvard Medical School. Consulting Physician Children's Hospital, Infants' Hospital and Beth Israel Hospital. Member, New England Pediatric Society, American Pediatric Society, Association of American Physicians and Boston Obstetrical Society. His subject is "The Necessary Requirements in a Minimum Diet for Infants and Children." Page 1057. Address 319 Longwood Avenue Boston, Massachusetts.

LENNON, WILLIAM G. A.B., A.M. Sc.D., M.D. Harvard University Medical School 1913. Instructor in Neurology, Harvard Medical School. Junior Visiting Neurologist Boston City Hospital. His subject is "The Use of Ergotamine Tartrate in Migraine." Page 1061. Address 909 Medical Building Boston City Hospital, Boston, Massachusetts.

The Massachusetts Medical Society

DISTINGUISHED SPEAKERS FOR THE ANNUAL MEETING

THE Annual Dinner of the Massachusetts Medical Society will take place on June 5, 1934 at 7 P M, in the Ballroom of the Hotel Bancroft, Worcester It is the chief social function of the Society In recent years, however, the attendance has been disappointingly small, possibly because the charge has been high for these times, possibly because the names of the speakers have not been made public

This year the tickets have been reduced to two dollars, and an excellent dinner will be served

The President of the Society has announced that the following distinguished speakers will be his guests

His Excellency The Governor of Massachusetts

His Honor The Mayor of Worcester

The Honorable James M Morton, Jr,
Judge of the United States Court of Appeals

The Right Reverend Henry K. Sherrill,
D D, Episcopal Bishop of Massachusetts

Dr Lewis Perry, Headmaster of Phillips Exeter Academy

It is also to be remembered that the Shattuck Lecture on Monday evening will be given by Dr Warfield T Longcope, Physician in Chief, The Johns Hopkins Hospital and Professor of Medicine of Johns Hopkins University School of Medicine His subject will be "The Importance of Disturbances in Nutrition in Oedematous States"

Dr Lincoln Davis, President of the Boston Medical Library and Consulting Surgeon, Massachusetts General Hospital, will present the Annual Discourse on Wednesday at 1 P.M His subject will be "The Objectives of Medical Progress"

With this impressive list of speakers, a large registration of the Fellows of the Society is reasonably to be expected

THE DANGER OF DINITROPHENOL AS A REDUCING AGENT

THE World War through the extensive manufacture of trinitrotoluol and related products served to call attention to the marked toxic character of these substances Their absorption was characterized by extensive liver damage, pigmentation of the skin An accompanying increase in pulse rate and temperature emphasized their general biological effect in enhancement of oxidative processes

Dinitrophenol, a closely related compound to TNT, has long been known in the laboratory but only recently has been brought to popular attention through the articles by Cutting and Tainter^{1 2} in the *Journal of the American Medical Association* These articles emphasized the value of this chemical as a metabolism raising agent through acceleration of oxidative processes They brought forward strong evidence for its utility, raising the basal metabolic rate 30 to 50 per cent without symptoms Under ordinary conditions fat is apparently oxidized without the development of acidosis

Unfortunately strong emphasis was not laid on the toxicity of this compound although warning was given as to its danger Already cases of death due to its use are being reported here and abroad³

This drug has great potential danger because of a narrow margin between the toxic dose and the therapeutic dose Fortunately it is fairly rapidly excreted by the kidneys so the possibility of accumulative effects is relatively slight. In the cases of death thus far reported liver damage appears to be the outstanding factor

to previous partially controlled infection which suddenly lights up in a form too severe to be checked by our routine methods. The hope of preventing such catastrophes lies in the earlier detection of incipient infection—preferably in childhood, when the seeds of later trouble are generally sown. The new methods of taking x-ray pictures of large groups of school children at a minimum cost brings promise of a better defense against the tubercle bacillus than we have ever been able to set up before.

The cost of a well-organized tuberculosis program (excluding the cost of sanatorium care which is largely treatment rather than prevention) is less than 10 cents per year for each person in the gen-

No matter how much the budget is cut children must not suffer. This little boy is being protected against tuberculosis by having a tuberculin test.

eral population. The results far outweigh this in significant expenditure. We may illustrate by a single instance. The reduction in the death rate from pulmonary tuberculosis in Syracuse, N. Y., for the decade 1922-1931 as compared with the decade 1912-1921 amounted to a saving of 115 lives a year. This takes no account of the far greater savings accomplished between 1892 and 1912 but merely measures the additional accomplishment after a more intensive community program was inaugurated in 1923. On a conservative estimate based on tables of the value of a human life at different ages, this additional reduction amounted to an economic saving of over a million and a half dollars a year to the community—based on life-saving alone and with no allowance for the burdens of disability and medical care. The total cost of the enlarged and almost ideal tuberculosis-control machinery of Syracuse was less than twelve thousand dollars. By paying one dollar in taxes to the city and the Community Chest, Syracuse saved paying one hundred dollars in taxes to the tubercle bacillus.

The question then is not whether we shall pay taxes or not, but how much we shall pay and for what. We can contribute a small sum to our health departments and clinics and nursing associations and tuberculosis associations for prevention or we

can pay a much larger sum as a tax on unprevented disease for the care of the sick, the support of the invalid, the burial of the dead, and the loss of man power. We have reduced the tax levied by disease during the past thirty years to a fraction of what it once was. We cannot afford to let our progress be nullified by the panic parsimony which is the enemy of true economy. We must rather go on with all the weapons at our command to the ultimate conquest of tuberculosis. "A few cents for defense, rather than millions for tribute," might well be our motto. The tax laid upon human vitality by preventable disease is one which we can abate if we have the courage to support in this crisis the official and the voluntary health agencies which have defended us so successfully in the past.

CANCER CLINICS AT BOSTON AND PONDVILLE

On Wednesday April 11, 1934 the last of the three Cancer Clinics arranged for the season of 1933-1934 by the Cancer Committee of the Massachusetts Medical Society, was held at the Massachusetts General Hospital in Boston and at the State Cancer Hospital in Pondville. About forty-five of the physicians on the staffs of the organized Cancer Clinics in Massachusetts were in attendance.

The Clinic at the Massachusetts General Hospital began at 9:30 A.M. in the Surgical Amphitheatre, with an operative clinic. Dr. E. M. Daland operated for cancer of the lip with radical neck dissection.

Dr. Channing C. Simmons did a radical amputation for cancer of the breast and Dr. J. V. Meigs demonstrated the application of radium in the treatment of a case of cancer of the cervix of the uterus.

Demonstrations were then given in the Surgical Amphitheatre as follows. Dr. E. P. Hayden showed an unusual tumor of the mouth, which was removed beneath the angle of the jaw, and proved to be probably a fetal adenoma of the aberrant thyroid. He also demonstrated the specimen of a branchial cyst which he had recently removed by operation.

Dr. E. M. Daland demonstrated a plastic operation for cancer of the lip and showed a case of extensive lymphangioma.

Dr. Grantley W. Taylor showed a case of disease of the ulna due to syphilis in which the differential diagnosis of bone sarcoma was suggested by the x-ray plates. Also an advanced and inoperable case of cancer of the breast in a young woman who was given x-ray treatment to produce an artificial menopause. He also demonstrated a case of advanced cancer of the tonsil which had had (1) preliminary x-ray radiation, (2) a dental cleansing of the month followed by (3) a two-thousand r unit treatment with x-ray, and (4) the insertion of radium seeds. This treatment produced a severe reaction followed by marked symptomatic improvement. He also demonstrated another case of inoperable cancer of the

MISCELLANY

ONE WAY TO REDUCE TAXES

BY DR. C. E. A. WINSLOW*

The first definition of a "tax" is a "contribution levied on persons, property, or business for support of government." A second meaning of the word is a 'strain or heavy demand' upon a person or a community. We hear a great deal today about the first kind of taxes. It might be wise to give some thought to the second.

From the standpoint of "strain or heavy demand" some of our most exacting tax collectors are the germs of the communicable diseases. In 1900 the bacillus of tuberculosis taxed the people in the United States to the tune of 195 lives for every hundred thousand persons in the population. That is this tax collector took the life of one person out of every 500 each year. In addition it collected the cost of medical and hospital

care and the cost of supporting in partial or complete idleness at least one person out of every 150.

By 1930 the death rate from tuberculosis† had fallen from 195 to 67 per 100,000. We had reduced the tax paid to this public enemy to one life out of every 1500 persons in the population with a similar reduction of two-thirds in the burden of sickness and disability. This is a sort of tax reduction which is well worth while.

Courtesy Henry Street Visiting Nurse Service

Public health is not just a vague name to people who are familiar with the Public Health nurse

How has this result been accomplished? By legislative machinery for the reporting of cases, by segregating or educating the consumptive so as to avoid infection of others, by eradication of bovine tuberculosis and pasteurization of milk, by public health nursing service to seek out contacts and early cases and bring them under medical care, by clinic service for early diagnosis by sanatoria for treatment, and by systematic follow up and supervision of the arrested case to hold the disease process under control. Simple, efficient, well tried public health machinery has accomplished the task. Its efficacy has been fully tested during the past three years when the potential effects of the depression upon the death rate have been warded off except in certain relatively small sections of the population where deprivation has been greatest. It is neither chance nor some hypothetical biological change which has brought about results for these results, in individual communities, have again and again been shown to vary in relation to the provision of community machinery for controlling the disease.

Recently, a new weapon has been placed in our hands. Experience has shown that many of the deaths which still occur from tuberculosis are due

*Professor of Public Health School of Medicine Yale University

†Based on figures for Registration States of 1900

or susceptibility to cancer in certain persons, or else that the action of some factor favoring the development of malignancy is of importance

The multiple cancers occur at practically the same age as do single cancers, and the average duration from the onset of the earlier tumor to death is about three years

The lesson to be drawn from these findings is that even though a person has been cured of cancer

he is not free from danger of that disease in fact he is three times more likely to develop a new cancer than a person who has never had cancer

CORRESPONDENCE

TRIBUTES TO THE MEMORY OF DR. WILLIAM HENRY WELCH

May 7, 1934

Editor *New England Journal of Medicine*

There are so many things to be said of Dr. Welch that one must exercise great restraint not to talk about him too much. To the student who knew him

only as a lecturer, perhaps the marvelous amount of information he possessed was most impressive but ter acquaintance revealed the remarkably clear mind, wide outlook and sound judgment. A quiz by Dr. Welch was always welcomed by the students because they were sure he would be not only charitable to ward their ignorance but most helpful in suggesting new points of view new lines of investigation, and hitherto unknown sources of information.

His positive and considerable contributions to sci

pharynx and palate of Grade II Malignancy in a man, which also improved under the plan of treatment used in the previous case. Dr Taylor also spoke of the neurosurgical relief of pain by alcoholic injection or resection of the branches of the fifth nerve. The Clinic then was adjourned to Pondville, where a luncheon was provided by the courtesy of the State Department of Public Health.

The following short papers were given

Dr Grantley W Taylor—Cancer of the Mouth in Women

Dr Roger Graves—Treatment of Cancer of the Penis (Two cases shown)

Dr Joe V Meigs—Carcinoma of the Cervical Stump

Dr Ernest M Daland—Lymphatic Drainage in Cancer

Drs. Richard Dresser and Charles Dumas showed three cases that were receiving x ray treatment for cancer of the upper esophagus, cancer of the buccal mucosa and cancer of the tongue

Dr Daland showed two cases of extensive cancer of the lower lip, one before and one after operation, a rope graft under construction for a deformity of the buccal mucosa, and an extensive carcinoma treated by x ray, surgery, and a plastic operation

Dr Taylor showed an inflammatory type of cancer of the breast and another breast case with radium needles in situ.

Dr Meigs showed a patient six months pregnant with an early cancer of the cervix and invited discussion as to the proper treatment.

Dr Graves showed a cancer of the prostate after perineal prostatectomy

Dr Merrill demonstrated a lymphoma case and a possible cancer of the lung

The residents showed a melanotic sarcoma of the thigh, a cancer of the jejunum (postoperative)

The meeting adjourned at 5 00 P M

On Tuesday, April 17, by invitation of the Lawrence Cancer Committee, seventeen members of the Essex North District attended the cancer clinic where Doctor Channing Simmons acted as consultant.

Multiple Cancers

The study of multiple primary malignant tumors has gradually shifted from the mere accumulation of case records to a comprehensive study of the implications of this somewhat unusual occurrence. Interest is no longer so much aroused by the mere occurrence of multiple cancers. The significance of the frequency or infrequency of multiple tumors now holds the center of the stage, as occurrence of these tumors may throw light on the but vaguely understood problems of resistance or susceptibility to cancer. Several comprehensive studies of the subject have been made, one of the first being that of Major¹, followed by Owen², and the most recent by Warren and Gates³. In addition to these a special study of multiple cancers of the mouth based on material from the Huntington Hospital, has been

made by Lund⁴, whose findings are in essential accord with those of Warren and Gates

In the paper by the latter authors, 1259 cases of multiple malignant tumors are collected from the literature, together with their own cases

Studies of the frequency of this condition are even more relatively unsatisfactory, as various authors differ considerably in the criteria that they lay down for the definition of this condition. The most rigid criteria are those of Billroth, that each tumor must have a different histologic appearance, that the tumors must arise in different locations, and that each must produce its own metastasis. This last requirement particularly rules out a very large number of cancers and results in a falsely low recording of the incidence of multiple malignant tumors. A perhaps fair standard is that set up by Warren and Gates, namely, each of the tumors must present definite evidence of malignancy, each must be distinct, and the probability of one being a metastasis of the other must be excluded

Some patients show an extraordinarily large number of different cancers, the most numerous being a case reported by Rappin⁵, who showed over 200 separate carcinomata.

Up to 1932, 111 cases of three or more multiple malignant tumors had been reported. Double cancer is, of course, much more frequent than this first group. Among the double cancers multiple cancers of the gastrointestinal tract are particularly frequent. This is perhaps caused by the frequent origin of carcinoma from mucosal polypi of the intestine. Warren states he has seen not infrequently multiple cancers of the large bowel associated with multiple polypi.

In the different series of cases reported in sufficient detail to estimate the frequency of this condition the variation is strikingly wide. Some authors find the multiple cancers to run less than one per cent of all malignant cases, while others find as high as over four per cent. In general, with due regard to the material utilized, about three per cent of all cases of cancer show more than one malignant tumor

Whether this percentage is higher or lower than that of chance is, of course, of real importance as indicating whether the person with one tumor is more than normally likely to have a second, that is, unusually susceptible to the disease, or is less than normally likely to develop a second cancer, that is, abnormally resistant to the disease

To calculate accurately the occurrence of multiple cancer on the basis of chance alone is extraordinarily difficult, yet this must be done to establish a norm. Such a norm has been established, though not with complete accuracy. Multiple cancers are found on the basis of this calculated norm to occur about three times as frequently as they would be expected to on the basis of chance alone, allowing for a large number of corrections. It may be definitely concluded, therefore, that there is some predisposition

Grim Reaper has signalled his coming, but nevertheless there are still many things and people worth talking and reading about and many, many memories to recall and recount.

And so we leave him — among his friends and his flowers — (on his eightvfourth birthday so many were sent that he ordered them distributed through all the wards of the hospital) and his marvelous memories memories of a long life wholly devoted to service for his fellow man, and influential beyond that of all others

ANONYMOUS

FREE LUNG DEFLATION TREATMENT

The Central New England Sanatorium, Inc.,
and Industrial Colony
Rutland, Massachusetts

May 1, 1934

Dear Mr Editor

We wish to call attention to the physicians of New England that we can accept their cases of early tuberculosis of the lung for deflation treatment without cost of any kind to the patient. We propose to keep these patients at the sanatorium for ten days or two weeks and then return them to the family physician for refills and further care. We sincerely hope that the family physician will present himself at the sanatorium where he will be given a demonstration of the technique of the operation and the technique of refills.

Application should be made to the Medical Director, Dr Bayard T Crane, Rutland Mass Tel Rutland 124

Truly yours

WALTER C BAILEY M.D., President

This is to inform you that at a meeting of the Board of Registration in Medicine held April 26 1934 the license of Dr Percy Whitman Carr of Hyde Park, Boston, was revoked for conviction in court for administering medicine to produce a miscarriage

Very truly yours

STEPHEN RUSHMORE, M.D., Secretary

MAY THE DOCTOR REMOVE THE QUARANTINE CARD?

To the Editor

In the issue of May 3 of the *New England Journal of Medicine* an Anonymous M.D. comments on a discussion that followed an address by Dr Willinsk

on the Relation of Public Health to Private Practice. Says the "Anonymous"

The discussion that followed was illuminating. One physician said that he should (for the price of a visit) be allowed to take down a measles quarantine card rather than have that service performed by a public health nurse. Does he not realize that it is because of that attitude that he is not employed more? If he were a layman would he feel that it was fair to have to pay for the visit of a supposedly skilled man to have that unskilled function performed?"

The writer of this letter was the first one to discuss the paper and he was the one who objected to the Board of Health's policy of having a quarantine card removed by a nurse without hearing first from the attending physician. There was no mention on my part of pecuniary considerations. It was the self respect and the dignity of the profession I was after. I maintained that a physician is certainly more qualified to judge than a nurse when his measles scarlet fever, or any other reportable case is ready for discharge. The nurse's function was always considered to carry out the physician's orders, but never to make diagnoses for him.

It is not a matter of the physical removal of the quarantine card. It is the judgment as to when this removal should occur. I shall gladly grant the first one to the nurse when the second is performed by the attending physician. Until recently such was always the policy of the Boston Board of Health. Why the change now?

M J KONIKOW M.D.

Urotropin Tablets 7½ grains (0.5 Gm)

entific knowledge were made in the earlier years of his activity, but it was in the field of the intangible that he was most powerful. He was a great university teacher, not in the Roman sense of "discipline," which, however, he appreciated but in the Athenian sense of "inspiration," possessing a most vigorous and stimulating mind. He was an important member of that small group who placed the study of medicine on a university basis in this country. He said that the secret of keeping young was to acquire a new technic. In any case, he remained young and was successively Professor of Pathology, Director of the School of Hygiene and Public Health, and Professor of the History of Medicine.

To those who had the privilege of the friendship of Dr. Welch he will always be the great humanist. Life became better because one had shared it, though in slight degree only, with him. One of the traditions is that he never spoke ill of any man, and his generous charity was but one of the manifestations of a rich and charming personality. He was in the great tradition, and his memory will be cherished always by his pupils with deep affection.

Yours truly,

STEPHEN RUSHMORE, M.D.

520 Commonwealth Avenue, Boston

May 4, 1934

Editor, *New England Journal of Medicine*

In my search for information concerning medical schools, it was natural for me to turn to the family physician who had inspired me to study medicine. His statement was "try to get into the school where Dr. William H. Welch teaches, nothing else matters." This in a line shows the tremendous influence at that time of this great man throughout the country.

During my four years in the Johns Hopkins Medical School, Welch was a great power. At no time did any student lose an opportunity to listen to anything he had to say. Occasionally there would be a chance to see him do an autopsy, hear him give a lecture or a quiz. Often an informal discussion, not always medical but invariably instructive and pleasing. The fondest memories, however, are those of "Popsy's" little summaries of the important lectures and demonstrations. Usually the student was lost in a maze of technicalities and would have derived small benefit in many instances had not Dr. Welch told us in a few simple words, what it was all about.

He was adored by all of us and we are grateful for his long and useful life.

Yours truly,

ARTHUR W. ALLEN, M.D.,
Class of 1913

264 Beacon Street, Boston

WILLIAM HENRY WELCH

1915—Baltimore. The laboratory, Johns Hopkins Hospital, the weekly clinical pathological conference. Around the central table "pipe stand" seats are crowded with clinical clerks, interns, assistants

from all departments of the hospital. In chairs on the floor are department heads — Halsted, Kelly, Howland, Thayer, Barker, Meyer and among them benign, alert, genial "Popsy" Welch, bright of eye, pointed of beard and rotund of abdomen.

The history of the patient is presented by the intern, a case of cirrhosis of the liver with jaundice. The description of the autopsy follows by the resident pathologist. Organs are demonstrated and microscopic slides shown on the screen. The case is discussed in general and then follows a summary by Dr. Welch in his judicial, crystal clear words, interspersed with many remarks concerning the etiology of liver disease. The various recent important articles on the subject, quoting both writer and journal, and something of the history of the development of the most plausible explanation of jaundice.

Or again, it is a beautiful spring evening and the Pi Theta Phi Club (a student society) is having its annual party on board the "Kitty Knight," a disreputable but long lived and famous Chesapeake Bay steamboat. Students are everywhere, and also a goodly sprinkling of faculty, among them "Popsy." Supper consists mostly of "Wienies" and beer, dispensed by the ubiquitous Louis Hanselmann.

Soon everyone crowds forward to the cabin to get seats for the play. Dr. Welch has but recently returned from a trip to China and Japan, made with Dr. Flexner, in the interest of medical education in the East, and the title of the play this year is "Popsy in the Orient." The cast is wholly in Chinese costume and the antics of the two students who impersonate Dr. Welch and Dr. Flexner, so humorous and in spots so lacking in reserve that the show "brought down the house." At its finish Dr. Welch in his so characteristic, dry humor made a few congratulatory remarks, coyly disclaiming for his friend Dr. Flexner and for himself any such actions while away, as had been suggested by the skit.

1923—London. The marvelous Jacobean guild hall of the Merchant Tailors on Threadneedle Street in the "City" is resplendent with lighted torches and dining tables round which are gathered about three hundred 'old students' of St. Bartholomew's Hospital. It is their dinner held during the "Solemnities" which celebrate the eight hundredth anniversary of the founding of the hospital. At the high table alongside dignitaries of church, state, and medicine sits Popsy, representing the General Education Board and the American Universities. His dignified and very forceful speech pointing out the many bonds uniting America with England and emphasizing the fact that science and the search for truth has no boundaries, geographical or otherwise, was by far the best of the evening.

1933—A sunny afternoon in Baltimore. In a hospital bed sits 'Popsy,' smoking the beloved cigar surrounded by books and flowers in every available space. He has grown a bit gaunt, for at last the

Grim Reaper has signalled his coming, but nevertheless there are still many things and people worth talking and reading about and many, many memories to recall and recount.

And so we leave him — among his friends and his flowers — (on his eighty fourth birthday so many were sent that he ordered them distributed through all the wards of the hospital) and his marvelous memories, memories of a long life wholly devoted to service for his fellow man, and influential beyond that of all others

FREE LUNG DEFLATION TREATMENT

The Central New England Sanatorium, Inc
and Industrial Colony
Rutland, Massachusetts

May 1 1934

Dear Mr Editor

We wish to call attention to the physicians of New England that we can accept their cases of early tuberculosis of the lung for deflation treatment without cost of any kind to the patient. We propose to keep these patients at the sanatorium for ten days or two weeks and then return them to the family physician for refills and further care. We sincerely hope that the family physician will present himself at the sanatorium where he will be given a demonstration of the technique of the operation and the technique of refills.

Application should be made to the Medical Director Dr Bayard T Crane, Rutland Mass. Tel Rutland 124

Truly yours,

WALTER C BAILEY M D, President
BAYARD T CRANE, M D Medical Director

OFFICIAL ACTION OF THE BOARD OF REGISTRATION IN MEDICINE

The Commonwealth of Massachusetts
Department of Civil Service and Registration
Board of Registration in Medicine
State House, Boston

May 2 1934

New England Journal of Medicine

This is to inform you that at a meeting of the Board of Registration in Medicine held April 26, 1934, the license of Dr Percy Whitman Carr of Hyde Park, Boston, was revoked for conviction in court for administering medicine to produce a miscarriage.

Very truly yours

STEPHEN RUSHMORE, M D, Secretary

MAY THE DOCTOR REMOVE THE QUARANTINE CARD?

To the Editor

In the issue of May 3 of the *New England Journal of Medicine* an 'Anonymous' M D comments on a discussion that followed an address by Dr Wilinsky

on the Relation of Public Health to Private Practice. Says the "Anonymous"

"The discussion that followed was illuminating. One physician said that he should (for the price of a visit) be allowed to take down a measles quarantine card rather than have that service performed by a public health nurse. Does he not realize that it is because of that attitude that he is not employed more? If he were a layman would he feel that it was fair to have to pay for the visit of a supposedly skilled man to have that unskilled function performed?"

The writer of this letter was the first one to discuss the paper and he was the one who objected to the Board of Health's policy of having a quarantine card removed by a nurse without hearing first from the attending physician. There was no mention on my part of pecuniary considerations. It was the self-respect and the dignity of the profession I was after. I maintained that a physician is certainly more qualified to judge than a nurse, when his measles, scarlet fever, or any other reportable case is ready for discharge. The nurse's function was always considered to carry out the physician's orders, but never to make diagnoses for him.

It is not a matter of the physical removal of the quarantine card, it is the judgment as to when this removal should occur. I shall gladly grant the first one to the nurse, when the second is performed by the attending physician. Until recently such was always the policy of the Boston Board of Health. Why the change now?

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

535 North Dearborn Street, Chicago III,
April 30, 1934

Managing Editor,

The New England Journal of Medicine,

In addition to the articles enumerated in our letter of March 31 the following have been accepted:

Cheplin Biological Laboratories Inc

Ampule Solution Procaine Hydrochloride 2 Per Cent 1 cc.

Ampule Solution Procaine and Epinephrine 3 cc

Ampules Bismuth Subsalicylate 2 Grains (0.13 Gm) in Oil, 1 cc

Ampules Solution Mercury Succinimide 1/6 Grain (0.01 Gm), 1 cc

Lederle Laboratories

Refined Diphtheria Toxoid (Alum Precipitated)

Schering & Glatz, Inc

Urotropin

Urotropin Tablets, 5 grains (0.3 Gm)

Urotropin Tablets 7½ grains (0.5 Gm)

entific knowledge were made in the earlier years of his activity, but it was in the field of the intangible that he was most powerful. He was a great university teacher, not in the Roman sense of "discipline," which, however, he appreciated but in the Athenian sense of "inspiration," possessing a most vigorous and stimulating mind. He was an important member of that small group who placed the study of medicine on a university basis in this country. He said that the secret of keeping young was to acquire a new technic. In any case, he remained young and was successively Professor of Pathology, Director of the School of Hygiene and Public Health, and Professor of the History of Medicine.

To those who had the privilege of the friendship of Dr. Welch he will always be the great humanist. Life became better because one had shared it, though in slight degree only, with him. One of the traditions is that he never spoke ill of any man, and his generous charity was but one of the manifestations of a rich and charming personality. He was in the great tradition, and his memory will be cherished always by his pupils with deep affection.

Yours truly,

STEPHEN RUSHMORE, M.D.

520 Commonwealth Avenue, Boston

May 4, 1934

Editor, *New England Journal of Medicine*

In my search for information concerning medical schools, it was natural for me to turn to the family physician who had inspired me to study medicine. His statement was "try to get into the school where Dr. William H. Welch teaches, nothing else matters." This in a line shows the tremendous influence at that time of this great man throughout the country.

During my four years in the Johns Hopkins Medical School, Welch was a great power. At no time did any student lose an opportunity to listen to anything he had to say. Occasionally there would be a chance to see him do an autopsy, hear him give a lecture or a quiz. Often an informal discussion, not always medical but invariably instructive and pleasing. The fondest memories, however, are those of "Popsys"—little summaries of the important lectures and demonstrations. Usually the student was lost in a maze of technicalities and would have derived small benefit. In many instances had not Dr. Welch told us in a few simple words, what it was all about.

He was adored by all of us and we are grateful for his long and useful life.

Yours truly,

ARTHUR W. ALLEY, M.D.,
Class of 1913

264 Beacon Street, Boston

WILLIAM HENRY WELCH

1915—Baltimore. The laboratory, Johns Hopkins Hospital, the weekly clinical pathological conference. Around the central table, 'pipe stand' seats are crowded with clinical clerks, interns, assistants

from all departments of the hospital. In chairs on the floor are department heads—Halsted, Kelly, Howland, Thayer, Barker, Meyer and among them benign, alert, genial "Popsy" Welch, bright of eye, pointed of beard and rotund of abdomen.

The history of the patient is presented by the intern, a case of cirrhosis of the liver with jaundice. The description of the autopsy follows by the resident pathologist. Organs are demonstrated and microscopic slides shown on the screen. The case is discussed in general and then follows a summary by Dr. Welch in his judicial, crystal-clear words, interspersed with many remarks concerning the etiology of liver disease, the various recent important articles on the subject, quoting both writer and journal, and something of the history of the development of the most plausible explanation of jaundice.

Or again, it is a beautiful spring evening and the Pithectomy Club (a student society) is having its annual party on board the 'Kitty Knight,' a disreputable but long-lived and famous Chesapeake Bay steamboat. Students are everywhere, and also a goodly sprinkling of faculty, among them "Popsy." Supper consists mostly of 'Wienies' and beer, dispensed by the ubiquitous Louis Hanselmann.

Soon everyone crowds forward to the cabin to get seats for the play. Dr. Welch has but recently returned from a trip to China and Japan, made with Dr. Flexner, in the interest of medical education in the East, and the title of the play this year is "Popsy in the Orient." APPLICATION FOR MEMBERSHIP

All male Fellows of the American Medical Association are eligible and cordially invited to become members of the A. M. G. A. Write the Executive Secretary, Bill Burns, 4421 Woodward Avenue, Detroit, for an application blank. Participants in the A. M. G. A. tournament are required to furnish their home club handicap signed by the secretary. No handicap over 25 is allowed, except in the Kickers. No trophy is awarded a Fellow who is absent from the annual dinner.

The twentieth tournament of the American Medical Golfing Association promises to be a happy affair, attended by some two hundred medical golfers from all parts of the United States.

REPORTS AND NOTICES OF MEETINGS

THE WILLIAM HARVEY SOCIETY

The William Harvey Society met in the Auditorium of the Beth Israel Hospital on April 13. Dr. Albert A. Epstein of New York City spoke on the "Disease of the Kidney in General Practice."

Dr. Epstein limited himself to a few of the more important processes that take place in kidney disease. He pointed out that the pathologist has helped to confuse the subject by describing the end products, while we are really interested in the processes by which these end results in the kidneys are obtained.

The question of albuminuria is an important one, though poorly understood. Albumin in the urine includes a variety of protein substances. The presence of these substances in the urine does not necessarily mean kidney disease, for example, it is normal to have an albuminuria after cold baths during or after severe exercise, and in students at examination time. Albumin, in these cases, represents the passage of protein from the blood as a result of circulatory disturbances. Orthostatic albuminuria, certain cases of severe lordosis or any of various causes of such lordosis may be the cause of albumin appearing in the normal urine. None of these conditions represent kidney disease, nor do they lead to kidney disease.

The presence of red blood cells, white blood cells and casts are of much more significance, though even they may not represent kidney disease since they may arise from other parts of the urinary tract, as is the case with numerous calcium oxalate crystals which traumatize the ureters and cause an inflammation together with a mechanical effect on the tubules.

The clinical condition known as nephrosis presents a urinary picture in which there is the passage of varying amounts of albumin. This loss of protein may amount to as much as one or two ounces of albumin a day. The normal plasma protein varies from six to eight and one-half Gm per cent and this figure may be lowered to two Gm

per cent in a long-continued albuminuria. The repeated withdrawal of ascitic fluid will lead to the same low plasma protein content.

The first important clinical effect of such albuminuria is edema. This is caused by the fact that the osmotic pressure of the protein of the plasma has been so reduced that the blood pressure forces an abnormal amount of fluid into the tissue spaces. The fluid balance in the tissue spaces is upset in this manner whenever the protein falls below five Gm per cent, and the normal osmotic pressure which tends to hold the fluids in the vessels is no longer great enough to carry out its task. Furthermore, there is a reversal of the normal two-to-one albumin globulin ratio. This is because the albumin molecule is smaller than the globulin and passes through the kidney more easily, but the destruction of the tissue protoplasm also contributes considerably to this increase in globulin.

In albuminuria fats are mobilized in the blood and represent the lipoids that are closely associated with the cells that break down in the general tissue disintegration—a disintegration that is caused by the edema and poor nutrition of the body cells. Another effect of albuminuria is that it causes, through the undernutrition of the cells, a fall in the B.M.R. which in turn causes changes in the thyroid suggesting an exhaustion.

In these cases of heavy albumin loss where the entire clinical picture is due to the effects of this loss, the institution of the proper treatment will bring about a cure unless infection sets in. Such treatment takes from six months to four years and consists in replacing the deficit of protein by a heavy protein diet as well as the use of large doses of thyroid, up to 60 grains a day, in order to facilitate the use of the protein. The lipid content of the blood is used as an index of how far the thyroid treatment can be carried since the overactivity of the thyroid causes a proportional decrease in blood lipids.

THE NEW ENGLAND ROENTGEN RAY SOCIETY

The New England Roentgen Ray Society held its meeting on Friday April 20, 1934, at 8:15 P.M. in the auditorium of the Beth Israel Hospital. Dr. Samuel A. Robins presided.

The first paper presented was by Dr. David Davis, who spoke on "Roentgenological Changes in the Heart after Total Thyroidectomy." The changes in the heart picture following total thyroidectomy depend in part on the condition of the heart before operation. A few patients with cardiac decompensation before operation have shown a decrease in the size of the heart shadow. Some have shown no change, probably due to a balancing of the effect of thyroidectomy with the improvement in the condition of the heart. Ordinarily, there is a slight increase in the size of the heart shadow after operation, this increase comes soon after the operation.

RECENT DEATHS

CUSHING—HAYWARD WARREN CUSHING, M.D., of 70 Commonwealth Avenue, Boston, died at his home, May 9, 1934. He was born in Boston in 1854, the son of Hayward and Harriett (Pierce) Cushing. He was fitted for college at the Boston Latin School, and graduated from Harvard College in 1877 and the Harvard Medical School in 1882. He studied later in England, Germany, and Austria. After returning to Boston he served on the staffs of the Boston Dispensary, the Carney Hospital, and later as surgeon to outpatients, and visiting surgeon to the Boston City Hospital. After concluding active service at the last named institution, he was given the title of consulting surgeon. He withdrew from active practice to a large extent in 1905 due to ill health.

He joined the Massachusetts Medical Society in 1881, and was a Fellow of the American Medical Association, a member of the Société Internationale de Chirurgie, the American College of Surgery, the Boston Surgical Society, the Boston Society for Medical Improvement, the American Society for the Advancement of Science, and the Boston Society of Medical Sciences. He held membership in the Harvard Club, the Tavern Club, and the Oakley Country Club.

He is survived by his widow Mrs. Martha (Thompson) Cushing, and two daughters, Mrs. Helen C. Bird of Norwell, and Mrs. Elizabeth C. Carleton of Cambridge.

SCRIBNER—JAMES MERLE SCRIBNER, M.D., of 11 Kilgore Avenue, West Medford, formerly of Lowell, Massachusetts, died at his home, May 11, 1934. He was born in 1902, the son of Mr. and Mrs. Charles E. T. Scribner. His early education was acquired in the public schools of North Adams and Medford.

He engaged in premedical subjects at Tufts College and later graduated in Medicine from Tufts College Medical School in 1927 where he was president of the Phi Chi Fraternity. His internship was at the Lowell Corporation Hospital, and he later served as resident physician and superintendent. After the name of the hospital was changed to St. Joseph's he served as chief of the obstetrical service. He joined the Massachusetts Medical Society in 1927, and was a Fellow of the American Medical Association. He was a junior member of the American College of Surgeons and was affiliated with the Masons and Elks. He is survived by his parents and two brothers, Dr. Edwin M. Scribner and Charles E. Scribner.

SLATE—AMES WILSWORTH SLATE, M.D., of 74 Oak Street, Indian Orchard (Lndlow), died at his home, May 11, 1934. He graduated from the Harvard Medical School in 1900.

NOTICE

AMERICAN MEDICAL GOLFING ASSOCIATION

The American Medical Golfing Association will hold its twentieth annual tournament at the Mayfield Country Club in Cleveland on Monday, June 11, 1934.

Thirty six holes of golf will be played in competition for the fifty trophies and prizes in the eight events. The trophies include the Association Championship for thirty six holes, gross, the Association Handicap Championship for thirty six holes net, the Choice Score Handicap Championship for thirty six holes gross, the low gross Eighteen Hole Championship, the low net Eighteen Hole Handicap Championship, the Maturity Event limited to Fifties over 60 years of age, the Oldguard Championship limited to competition of past presidents, and the Kickers' Handicap. Other events and prizes will be announced at the first tee.

Dr. Homer K. Nicoll of Chicago is president and Dr. Charles Lukens of Toledo and Dr. John W. Powers of Milwaukee are vice presidents of the American Medical Golfing Association, which was organized in 1915, by Dr. Will Walter, Dr. Wendell Phillips and Dr. Gene Lewis, and now totals 1,100 members representing every state in the union. The living past presidents include Dr. Wendell Phillips of New York, Dr. Thomas H. Hubbard of Toledo, Dr. Fred Bailey of St. Louis, Dr. Edward Martin of Philadelphia, Dr. Robert Moss of San Antonio, Dr. Carlton Wallace of New York, Dr. Will Walter of Chicago and Charlottesville, Va., Dr. James Eaves of San Francisco, Dr. Chester Brown of Danbury, Conn., Dr. Samuel Childs of Denver, Dr. W. D. Sheldon of Rochester, Minn., Dr. Walter Schaller of San Francisco, Dr. Edwin Zabriske of New York, Dr. Frank Kelly of Detroit and Dr. John Welsh Croskey, Philadelphia.

CLEVELAND COMMITTEE

The Cleveland Committee is under the chairmanship of Dr. John B. Morgan, 1301 Medical Arts Building, Cleveland, Ohio. He will be assisted by Drs. R. H. Birge, A. V. Boysen, E. F. Freedman, F. T. Gallagher, Secord Large, E. P. McNamee, J. J. Marek, Theodore Miller, U. V. Portman and M. A. Thomas.

The Mayfield Country Club of Cleveland is described by Chairman Morgan as 'probably the finest course in the district, and certainly one of the most interesting. Many championships have been held on this course and I am sure the visiting doctors will be delighted with it in every sense of the word. It has a most beautiful club house, and we can promise a merry nineteenth hole and a dinner fit for a champion.'

term of secretary treasurer, recently made vacant through the decease of Mr George T Lennon who had served faithfully for many years

Dr Francis P Denny, as the chairman of the committee to arrange for certain sections within the organization reported that he had received requests for several sections as follows Health Officers 41 Laboratory 25 Milk and Food Inspection 25 Sanitary Engineer, 13 Epidemiology, 31 Public Health Nursing 14

The following papers were read Mr David A. Chapman, on Air Pollution Prof Philip Drinker on 'The Cause and Prevention of Silicosis' Prof William F Wells on Air Bacteriology Following the reading of these papers a general discussion was entered into by many of the members present. A rising vote of thanks was tendered to the gentlemen who read the papers

JOHN J McGRATH Agent

FAULKNER HOSPITAL CLINICAL MEETING

On Thursday afternoon May 3rd at 5 00 P.M. the regular monthly clinical meeting of the Staff of the Faulkner Hospital was held at the hospital

Two unusually interesting cases which had come to autopsy during the month were discussed

In one case the outstanding features were pronounced anemia, ulcerations around and in the anus and peculiar degenerative lesions of the skin At the time the patient first came under observation there was a marked leukopenia so that at first the case was thought to be one of agranulocytosis During the patient's stay in the hospital however with the only specific treatment consisting in injections of liver extract the leukocyte count rose from 650 to around 18 000 At autopsy it was found that the case was one of aleukemic leukemia.

In the other case the outstanding symptom was loss of weight with slight fever X-ray pictures of the pelvic bones showed many lesions which suggested metastatic malignancy of the type in which there was increase in density in the shadow cast Shortly before death this patient had considerable precordial distress and the pulse rate became markedly accelerated and irregular in rhythm At autopsy there was no evidence of malignancy upon gross inspection and the bones which showed the increase in shadow were softer than usual. The pericardial cavity was filled with blood but it was not evident from where the blood came On microscopic examination however all the organs of the body were filled with an adenocarcinoma. There is still doubt in the mind of the pathologist in regard to where the tumor originated The structure of the adenocarcinoma is consistent with origin in the biliary passages but evidence of tumor was present in the ovarian tissue which is an unusual organ for metastasis from a tumor originating in the liver

Dr William W Howell then gave a short discussion on The Methods of Handling Difficult Problems in Infants and Children and in a very amusing

manner told of some of his personal experiences in which common sense and judgment seemed to have been lost sight of by physicians and parents in the handling of the individual problem Although not in any way trying to detract from the value of various diagnostic and therapeutic procedures which have been recently introduced into the practice of pediatrics, he sounded a note of warning that in some instances too many of these procedures may be tried upon the individual patient and too often there is a lack of judgment on the part of the physician in regard to how many of these different procedures should be used He emphasized the fact that up to the present time a great majority of children seem to grow up into healthy adults without worrying over a slight loss of weight for a day or so after birth or feeling that dehydration should be guarded against. One gathered also from listening to him that possibly the great majority of babies would do as well without the curiosity of the physician being satisfied in regard to the thymus gland by an x-ray study shortly after birth

The final clinical meeting of the season will be held on Thursday June 7th at 5 00 P.M., at the hospital. In addition to the usual clinical pathological conference Dr Edward L Young Jr, who was scheduled to speak at the April meeting, but was unable to do so will discuss 'Some of the Difficulties of Gallbladder Diagnosis' All physicians who are interested are cordially invited.

THE CARNEY HOSPITAL CLINICAL MEETINGS

On Wednesday morning April 25, the regular clinical monthly meeting was held at the hospital. About forty visiting physicians and members of the Staff were present

Dr A. McK Fraser did a cholecystectomy and drainage of common bile duct.

Dr Harold Lee did an open operation for fractures of both bones of forearm

The Day Clinic, which was well attended, started at 10 A.M. and lasted until 12 o'clock. During this time three members of the Staff gave short talks

Dr A. Leo Brett discussed certain types of foot strain associated with backache relieved by foot plates and demonstrated various forms of plates

Dr L. E Phaneuf discussed avoidable accidents in obstetrics

Dr A. McK. Fraser discussed care of patients before operations for gallbladder disease

The next clinical meeting will be held at the hospital on Wednesday the 23rd of May and at that meeting various operations will be performed by members of the Staff

A Day Clinic will be given by Drs Louis F Curran Daniel J Hogan, and Norman A. Welch of the Medical Department The subject presented will be Electrocardiography

coincident with the lowered metabolic rate Dr Davis reported fifteen patients with congestive heart failure in whom total thyroidectomy was followed by an increase in the heart shadow size and by clinical improvement. The myxedema heart was briefly discussed.

A paper on "Protracted Irradiation in Carcinoma of the Larynx" was presented by Dr Harry F. Friedman. He reported his results in the treatment of five cases of carcinoma of the larynx and pointed out that the intensity of irradiation in this disease should be influenced by the amount of calcification that is present in the laryngeal cartilages. Papillary types of carcinomata require the largest doses. The speaker showed slides demonstrating the site of irradiation and the subsequent skin reaction. He demonstrated two patients treated by x-ray with encouraging result. One patient has gone fourteen months without recurrence. Dr Friedman described another of his patients who was irradiated every day from 9 A.M. to 5 P.M. for thirty-five days. Aphonia follows the treatment with gradual improvement. Tracheotomy has occasionally been necessary because of the reaction. There is little discomfort from the skin reactions with no apparent untoward effects upon the thyroid gland.

Dr William S. Altman presented an interesting paper on "The Value of Lateral Views of the Rectum." It has been found from experience that the left lateral view gives the best results. The plates are best taken immediately after the sigmoid is filled and before the entire colon is filled, because loops of the latter may easily obscure lesions in the former. Dr Altman showed lantern slides demonstrating lesions in the sigmoid on the lateral view which had been entirely concealed in A.P. or P.A. views. Lateral views have proved useful in the demonstration and diagnosis of lesions of the descending colon.

The subject of "Roentgenological Explorations of the Biliary Ducts with Lipiodol" was discussed by Dr Louis Hermanson. The procedure has been reported only once by an observer in Argentina, and attempts are now being made at the Beth Israel Hospital to make it of practical use. Lipiodol is injected into the biliary ducts at the time of operation by means of a 14 gauge needle in quantities of 15 to 20 cc. There is no necessary modification of the operative procedure except that the drapes are sewed on rather than clipped. The picture thereby obtained is of considerable value to determine whether the common duct is to be explored, at least in the doubtful cases. X-rays may be taken at any desired interval after the operation as check ups.

Dr Leopold Brodny presented an interesting paper on Urethrography and illustrated it by means of lantern slides. Urethrography has been neglected largely because the urethra is so readily accessible to the urethroscope. The work started with Dr Cunningham in Boston in 1910 but the posterior urethra was not demonstrated by urethrography

until 1921. Any iodized oil may be used for the injection. After about 20 cc of the fluid has been injected, the x-ray film is exposed, but care has to be taken that the fluid continues to be injected. If the injection is stopped at the time the exposure is made, the posterior urethra shuts down and will not appear in the film. The position of the patient is important for good pictures. Lantern slides showing urethrograms in the presence of prostatic hypertrophy were projected on the screen. The splitting of the stream of injected material in the posterior urethra with hypertrophy of the middle lobe of the prostate was very clearly demonstrated. Urethrograms in patients with tabetic bladders show a characteristically funnel-shaped posterior urethra. The condition of the urethra after prostatectomy was illustrated. It was apparent that good functional results are not dependent exclusively on anatomical restoration. The internal sphincter is not essential for urinary continence. Urethrograms in the female were also demonstrated, showing anatomical variations, a case with a small diverticulum of the urethra, and a case with hypertrophy of the internal sphincter. The effect of straining on the position of bladder and urethra relative to the pelvis in cases with cystocele was shown very adequately by means of urethrograms.

The final paper was presented by Dr Samuel A. Robins who spoke on "Cystography and the Prostate." Cystography was first used at the beginning of this century and shortly thereafter attempts were made at demonstrating enlargements of the prostate by injection of air into the bladder. Solutions of the halogens were first used in 1919 in 25 per cent solutions. In his experience, Dr Robins has used 3 per cent solutions very satisfactorily. Various affections of the bladder were shown by means of lantern slides including hypertrophy, sacculation, pouching, and elevation of the base of the bladder. The characteristic "derby-shaped" appearance of the bladder with elevated base due to prostatic hypertrophy and obstruction was illustrated by numerous examples. Distinct trabeculation was shown in some of the slides presented, as well as small defects from hypertrophy of the median bar of the prostate and defects from the small fibrotic prostate. Dr Robins pointed out that by cystography it is impossible to make a diagnosis of carcinoma of the prostate.

Each of the papers was followed by a very brief discussion.

MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH

The Massachusetts Association of Boards of Health met on May 3 at the University Club, Boston.

Dr Henry D. Chadwick, Commissioner of the State Department of Public Health, was elected to membership on the Executive Committee. Mr. Donald G. Buckner was elected to fill the unexpired

term of secretary-treasurer, recently made vacant through the decease of Mr George T Lennon who had served faithfully for many years

Dr Francis P Denny, as the chairman of the committee to arrange for certain sections within the organization reported that he had received requests for several sections as follows Health Officers, 41 Laboratory 25 Milk and Food Inspection, 25, Sanitary Engineer, 13 Epidemiology, 31 Public Health Nursing 14

At autopsy it was found that the case was one of aleukemic leukemia

In the other case the outstanding symptom was loss of weight with slight fever. X-ray pictures of the pelvic bones showed many lesions which suggested metastatic malignancy of the type in which there was increase in density in the shadow cast. Shortly before death this patient had considerable precordial distress and the pulse rate became markedly accelerated and irregular in rhythm. At autopsy there was no evidence of malignancy upon gross inspection and the bones which showed the increase in shadow were softer than usual. The pericardial cavity was filled with blood but it was not evident from where the blood came. On microscopic examination, however all the organs of the body were filled with an adenocarcinoma. There is still doubt in the mind of the pathologist in regard to where the tumor originated. The structure of the adenocarcinoma is consistent with origin in the biliary passages but evidence of tumor was present in the ovarian tissue which is an unusual organ for metastasis from a tumor originating in the liver

Dr William W Howell then gave a short discussion on The Methods of Handling Difficult Problems in Infants and Children and in a very amusing

manner told of some of his personal experiences in which common sense and judgment seemed to have been lost sight of by physicians and parents in the handling of the individual problem. Although not in any way trying to detract from the value of various diagnostic and therapeutic procedures which have been recently introduced into the practice of pediatrics, he sounded a note of warning that in some instances too many of these procedures may be tried upon the individual patient and too often there is a lack of judgment on the part of the physician in regard to how many of these different procedures should be used. He emphasized the fact that up to the present time a great majority of children seem to grow up into healthy adults without worrying over a slight loss of weight for a day or so after birth or feeling that dehydration should be guarded against. One gathered also from listening to him that possibly the great majority of babies would do as well without the curiosity of the physician being satisfied in regard to the thymus gland by an x-ray study shortly after birth

The final clinical meeting of the season will be held on Thursday, June 7th at 5 00 P.M., at the hospital. In addition to the usual clinical pathological conference Dr Edward L Young Jr who was scheduled to speak at the April meeting, but was unable to do so will discuss 'Some of the Difficulties of Gallbladder Diagnosis'. All physicians who are interested are cordially invited

THE CARNEY HOSPITAL CLINICAL MEETINGS

On Wednesday morning, April 25, the regular clinical monthly meeting was held at the hospital. About forty visiting physicians and members of the Staff were present

Dr A. McK. Fraser did a cholecystectomy and drainage of common bile duct.

Dr Harold Lee did an open operation for fractures of both bones of forearm

The Dry Clinic which was well attended started at 10 A.M. and lasted until 12 o'clock. During this time three members of the Staff gave short talks

Dr A. Leo Brett discussed certain types of foot strain associated with backache, relieved by foot plates and demonstrated various forms of plates

Dr L. E. Phaneuf discussed avoidable accidents in obstetrics

Dr A. McK. Fraser discussed care of patients before operations for gallbladder disease

The next clinical meeting will be held at the hospital on Wednesday the 23rd of May, and at that meeting various operations will be performed by members of the Staff

A Dry Clinic will be given by Drs Louis F Curran, Daniel J Hogan, and Norman A. Welch, of the Medical Department. The subject presented will be Electrocardiography

MASSACHUSETTS SOCIETY OF
EXAMINING PHYSICIANS

ANNUAL MEETING

The Copley Plaza, Wednesday, May 23, 1934

Business Meeting 6 30 P M

Dinner at 7 P M sharp \$2.50 per plate

Election of Officers

Speakers

1. Dr. Joel E. Goldthwait, "Chronic Invalidism due to Joint Pathology"

2. Dr. Howard Thompson, "Medical Aspects of the Subject."

3. Dr. Carl Watson, "The Subject from the Osteopathic Point of View"

CADIS PHIPPS, M.D., *President*WM. PEARCE COUES, M.D., *Secretary*

AMERICAN PSYCHIATRIC ASSOCIATION

The ninetieth annual meeting of the American Psychiatric Association will be held at the Hotel Waldorf Astoria, New York City, May 28, 29, 30, 31, and June 1, 1934.

The program which includes addresses by eminent psychiatrists representing the several sections of the country is of especial interest.

There will be a scientific exhibit, motion pictures of hospital activities, and a commercial exhibit. Special rates are allowed by railroads. To secure these reduced rates, those who attend should obtain a certificate (not a receipt) for each ticket. One-way ticket should be bought to New York and on presentation of the certificate at headquarters registration the return ticket can be purchased at one third fare.

SOCIETY MEETINGS, CONGRESSES
AND CONFERENCES

May 18—The New England Roentgen Ray Society will meet at the Boston Art Club, Boston, at 8 P.M. The Annual Dinner will be held at the Boston Art Club at 6 45 P.M.

May 19—The New England Pediatric Society will meet at New Haven Conn. at 2 30 D.S.T. Information may be obtained from the Secretary, Dr. Gerald Hoeftel, 319 Longwood Avenue, Boston.

May 21, 24, 25—New England Heart Association. See page 1041, issue of May 10.

May 23—Massachusetts Society of Examining Physicians. See notice above.

May 23—The Carney Hospital Clinical Meeting. See page 1093.

May 26, 27, 28, and 29—The American Association on Mental Deficiency. Details may be obtained from the Secretary, Dr. Groves B. Smith, Godfrey, Illinois.

May 28, June 1—American Psychiatric Association. See notice above.

June 7—Faulkner Hospital Clinical Meeting. See page 1093.

June 7, 8, 9—Annual Meeting of the American Association for the Study of Gout will be held in Cleveland, Ohio. For details of the program apply to Dr. J. R. Yung, Terre Haute, Ind.

June 11—American Medical Golfing Association. See page 1090.

June 12—American Heart Association will meet at 9 30 A.M. at the Cleveland Hotel, Cleveland, Ohio.

July 24-31—The IVth International Congress of Radiology will be held in Zurich under the presidency of Professor H. R. Schnitz. General Secretary, Dr. H. E. Walther, Gloriastrasse 14, Zurich.

August 18 - September 30—Medical Study Trip to Hungary. See page 975, issue of May 10.

September 3-6—American Public Health Association at Pasadena, California. Dr. J. D. Dunshee, Chairman, Local Committee on Arrangements.

September 4, 5, 6—International Union Against Tuberculosis. For information address the National Tuberculosis Association, 450 Seventh Avenue, New York City.

NEW ENGLAND SURGICAL SOCIETY

NOTES ON GIANT-CELL TUMORS OF BONE AND CYSTS*

BY FREDERIC J. COTTON, M.D.†

IT is not my purpose here to do more than give the gross results of observation in this class of cases and some detail only in regard to individual cases that seem to me significant. The title is chosen because there present themselves to us a rather large proportion of cases that seem, offhand, to be giant-cell tumors. Careful study of history, physical findings and x-rays will give us a rough reclassification into typical and atypical cases, but, at least in the latter group, there are many errors. Therefore typical and atypical tumors and cysts (and the mistakes) will be considered together as a *clinical* grouping, not as if always related histologically at all.

The typical giant-cell tumor is familiar enough and perhaps some of us have swung too far in complacency as to the benign character of the growth. Sometimes we are reminded that the border-line of malignancy is a narrow one and that we really know but little about these growths. This type tumor is without significant history as to origin or course of the trouble until it is called to attention by a fracture through it. Typically these are infractions, cracks or crumplings only not in themselves important. In gross there is expansion of the bone in diameter, with a blunting of outlines notable if it is near the joint end of a shaft bone. There is no characteristic heat or vessel dilatation or change of color. Soft parts are not infiltrated. There is no tenderness unless there has been a trauma.

By x-ray we find a wide area of transparency, that is, bone loss definitely limited in area but usually without any dense surrounding layer. The area of absorption looks as if it had progressed, not from the centre outward as with osteogenetic sarcoma, more or less globular or oval, but as if it had pushed its way into the corners of the cancellated bone. Typically the area of defect is more or less traversed by trabeculations. This is not a reliable differentiation, diagnostically, against cyst, either way. Growth causes absorption of the cortex, sometimes entire. Protrusion through the periosteum or into a joint is not part of the type picture.

Exact x-ray diagnosis is only at times possible, but the common confusion is as between cyst and tumor. We may say with some confidence that we have a sarcoma or myeloma, or that we are dealing with *either giant-cell tumor or cyst*. We are not always certain, or always right.

Much has been made of the location, more than the facts seem to warrant.

Typically giant-cell tumors belong to shaft ends (not epiphyses) of the tibia or femur at the knee or the humerus high up, or the radius at the wrist, while cysts, at least of the "solitary cyst" type occur more away from the bone ends. In practice either may occur anywhere. We have cases of giant-cell tumor of radial and humerus midshaft.

In this small series are giant-cell tumors of the jaw of the scaphoid of the foot of a metatarsal, two of the phalanges of the hand, two metacarpal tumors, one case of a patella, one probable vertebral involvement*.

Tumors of the jaw, not in bone (epulis) are recognized, and in our series there are apparently typical tumors, without primary bone origin, in the pulp of a finger tip, at the end of a toe, in the capsule of an ankle joint. Apparently they may be anywhere save in the ribs and the skull.

On the other hand cysts in our series occurred in or close to the head of the femur in four cases, close to the knee in one, close to the tibial head in three, at the ankle in one close to the shoulder in two, once in a metacarpal and once in the pelvis. On the other hand, eight were shaft cysts. So the line is far from sharp.

Histologically the giant-cell tumor is a granulation tissue, a fibroblast mass studded with "foreign body" giant-cells (Mallory), vascular, without considerable mitoses. It is sharply different from the malignant type with "tumor" giant-cells. Mallory has a type case of this sort, a giant-cell growth, but with every histologic sign of malignancy. Broadly speaking, it is true that the tumor characterized by giant-cells of the "foreign-body type" (as Mallory has long called them) scattered thickly in the mass of fibroblast granulation, is in the vast

*Lewis Dean. Primary giant cell tumors of the vertebrae. J. A. M. A. 83:1224 (Oct. 18) 1924.

majority of cases benign Changes in tumor character are vastly rare, so rare that I think there is some doubt in the matter There have been a few cases of death, with metastases

One case can only be called malignant, but the impression gained in seeing it was of presumably embolic metastases in the lung, not generalizing, of unchanged histological character

Another, Case II, F F, died

CASE I, M—n

A girl of nineteen in 1925 after slight injury developed a tumor of the radius at the wrist which by March, 1926 became disabling Operated March 27, 1926 at the Massachusetts General Hospital Recurrence after two months Xray treatment, intensive but with no results Seen by me Dec 7, 1926 with a much expanded bone Skiagraph typical Operated on by me, Feb 14, 1927 Type tumor No cystic degeneration Cured and packed Healed quickly

Pathological report by Mallory of a typical "chronic inflammation with foreign body giant-cells Healing and partial bone repair"

Reoperated in July, 1927 for recurrence in region of the radial styloid

The pathological report was again of the typical tumor After this there was healing and at least no definite recurrence locally Early in December, 1927 she developed a cough and on Jan 3, 1928 there showed characteristic metastatic nodules in the lungs increasing rapidly in size to May, 1928 Then a quiescence of growth and symptoms but after xray treatment she grew worse and died in October 1928, three years after the recognition of the tumor I am afraid the xrays here did only harm

CASE II F F, Baddek Nova Scotia woman of 59, seen Jan 18 1930 In December, 1928 she had an epulis of upper jaw removed which was called a "sarcoma" and treated afterward with radium Examination showed tumors of the ulna at the right wrist, left patella and left lower jaw Curettage and the usual vaseline pack. All tumors removed were diagnosed as type giant cell growth by Mallory

All wounds healed there were no recurrences but a fresh tumor appeared in the right radius at the wrist doubtful when she was first sent home, rapidly growing a month later and operated in February, 1930 Tumors developed in the knuckles A third operative series was done in May, 1930 With in five months there was a spontaneous fracture of one tibia and a humerus broke as she fell

Tumors developed in both hands in the tarsus on one side in a fibula and in an ulnar shaft in hips etc Some of the growths were operated on in Nova Scotia She died Oct 11 1931 There had been an incredible number of growths a number of fractures Viosterol was used

In October 1930 I wrote Dr McMillan my conviction that this case belonged in the class of v Recklinghausens osteitis fibrosa cystica

In 1930 I knew nothing useful about the parathyroid relation to the condition

The first report is cited above The second operation brought a report from F B Mallory The picture was consistent with so-called 'benign giant cell tumor of bone'

Pathological report after the third operation from T Leary reads 'Benign giant-cell tumors of first right metacarpal, right ring finger and left hand'

One case showed clinically a queer type of recurrence late and fast with a histological pic-

ture suggesting a station on the border-line of malignancy

CASE III, M Q, a woman of 46 seen November 19, 1931 right knee lame for a month Tumor of the outer part of the head of the tibia seen by xray with slight infraction of the cortical layer but no trabeculations It looked like a cyst Operated on November 25, 1931 and it proved to be a tumor, which was cleaned out and packed in the usual way

Pathological Report "Two types of reaction. In one area the tissue is composed solely of newly growing fibroblasts growing without any characteristic arrangement" The other area a typical "giant cell" tumor No mitoses

Diagnosis Giant cell tumor, granulation tissue. (J Stewart Rooney)

She healed quickly, became active and well save for a developing high blood pressure which was successfully reduced

In August, 1933 a routine check xray showed a quick recurrence this two years after the first operation, and without warning symptoms

Operation August 15, 1933 showed the tumor to be seemingly a typical giant-cell but unusually vascular and like a myeloma The tumor was larger than at the first operation It was treated as usual and has done well, but the microscopic picture, giant cell again showed more mitotic figures than one likes Xray treatment promptly Judgment reserved

May 17 1934, no further recurrence

There are two cases recurring persistently that raise a suspicion of malignancy

CASE IV, L F, a colored man, aged 40 was admitted to the Hospital Sept 5 1928 Says he struck his wrist against a door three months ago Swelling appeared which grew rapidly

Examination shows the tumor at the lower end of the radius, typical except that it is tender

Xray showed a typical giant-cell for the lower two inches, extending close to the joint. There was a good deal of expansion

Operated on September 11, 1928 Typical tumor except for some tumor tissue externally, apparently oozed out through a small fracture line Usual routine

Pathological report of type tumor Cleaned up well but had a recurrence after about a year

Entered another service with a pretty large tumor at the wrist in April, 1930 and for some reason amputation was advised and done but the pathological report read Foreign body giant cells Blood pigment. Chronic inflammation new bone formation Picture consistent with so-called giant cell tumor (Mallory)

CASE V Case of Dr Hepburn's at the Boston City Hospital

Almost similar to the above, a giant cell tumor of the tibia high in a woman of 40 which recurred after seven years, but then reappeared within two months The leg was amputated in January, 1933 No recurrence as yet up to August, 1933 A giant cell tumor, no sign of malignancy histologically

These cases seem in no sense to be malignant as the term is used Recurrence may mean inefficient surgery

CASE VI H F

In 1920 at about six years of age had an abscess of the cheek. Six months later there was painless swelling of the jaw Seen a year later showed enlargement of the lower jaw from above the angle forward to the bicusplids

Operated by curetting and packing under the old technique It took nine months to heal

Two years later operated for recurrence It healed in two months

These were typical giant cell growths and so reported microscopically

An operation for scar keloid in 1924

Examined in May, 1933 No recurrence no deformity, almost invisible scar

In this case the operation was extensive and difficult and it obviously took two tries to get it all

No other cases have recurred, though one other was mistakenly opened up for what proved only a cyst-like pocket

CASE VII U a woman about 22 Tumor of the radius at the wrist. Operated as usual, healed but did not shrink down and xray was doubtful after three months Operated on no tumor found Went on to perfect healing No recurrence for two years at least. This was an unnecessary operation

There are not uncommon seeming transition forms, on the way from tumor to cyst

A notable example, already recorded, shows this very definitely

CASE VIII P S

Boy of five years Operated at the old Beth Israel Hospital for osteomyelitis It was not osteomyelitis and the pathological report from the Harvard Medical School was 'giant cell sarcoma malignant' which also it was not

Seen by me July 24 1929 then eleven years old History of slowly developing bowing and shortening of the right leg Then two inches short with upper end of tibia much broadened

Xray showed apparent multiple cysts and deformity of the epiphyseal line

Operation July 29, 1924

Three separate cysts occupying the whole head of the tibia close to the epiphysis No sign of any lining It was made into one cavity cleaned and filled with Horsley bone wax and closed

Prompt recovery with no recurrence

Oct 6 1924 it showed repair with absorption of the wax beginning

Kept track of to July 10 1929 at which time the transparent area (bone wax) showed in the xray as about half the mass put in

The epiphyseal line was more nearly flat and normal

Damage to the epiphyseal line may be chargeable to tumor involvement, quite as likely resulting from the first operation however

This case brings up definitely George Barrie's contention of years ago that giant-cell tumors were an "Hemorrhagic osteomyelitis"* forming the pseudo tumor, retrograding to the cyst

It is certain at least that the tumor may be the forerunner of the cyst and one sees occasional transition cases mostly cyst with giant cells in the organized more fibrosed wall or a fibrous lining to a cyst from which the giant-cells have disappeared

CASE IX M C. girl of 13 Operated on December 3 1932 No history till the bone broke with very slight trauma Tumor was at the distal end of the second metatarsal which was much expanded and broken across

Barrie George Multiple hemorrhagic foci in bone Ann. Surg. 1 551 (May) 1920

Usual operation save that the wound was closed over blood clot and not packed Traction to toe applied to maintain the shape of the bone Ideal result up to Sept 10 1933

Pathological Report

Sections show one portion of the cyst wall to be composed of fibrous tissue Other portions of the tissue are composed of cells apparently derived from fibroblasts, these cells growing in an irregular manner and numerous giant-cells are seen An occasional mitotic figure is also seen Diagnosis Giant-cell tumor of bone (J Stewart Rooney) In gross this was a cyst with 'tumor' lining or granulation lined cysts with considerable soft tissue which do not show characteristic giant cells in the mass

CASE X H

Aged five and a half years Operated at Beth Israel Hospital Jan 13 1931 Spontaneous fracture of the humerus Diagnosis from xray of giant cell tumor

Operation showed a cyst, with tissue lining Treated as usual and treated promptly

A residual cyst was opened up a year later, Jan 7 1932 and healed No recurrences to date

Microscopic examination showed no giant-cell tumor only chronic inflammation with new bone formation (M J Schlesinger)

Obviously the eighteen days old repair of the fracture overlaid any tumor pathology there may have been

CASE XI, T R of Waterville Maine boy of 16 Broke both bones of leg four weeks ago just below knee Pathology underlying the break not noted Seen Dec. 15 1931 Xray showed an oddly elongated atypical cyst Diagnosis of cyst tentative (Dr Paul Butler)

Operation Dec 17 1931 showed cyst with much tissue lining which was cleared packed healed and repaired Last year the boy ran the mile for his school

Pathological report showed repair changes chargeable to the fracture and besides this giant cells are seen and it is difficult to determine whether they are the giant cells characteristic of so-called giant cell tumor or whether they are the giant cells seen in cases of repair A very rare mitotic figure can be seen

Diagnosis Granulation tissue giant cell repair bone cyst (giant cell tumor) (J Stewart Rooney)

Examined in April 1934 No sign of recurrence

Of possible meaning is the internal pressure found in some cysts with minimal fibroblast cyst lining This tension is not easily understood

It is odd that just one of these cases is the only cyst that recurred

CASE XII D W Male Aged 40 Seen July 25 1928

Sudden onset of pain in hip ten days before severe increasing

Temperature 100 degrees Markedly sensitive hip Some muscle spasm Intensely painful Xray showed cyst in neck of femur Unusual pain and temperature suggested a side diagnosis of Brodie's abscess

Operation Faulkner Hospital July 28 1928 On cutting down to the bone fluid was extruded under pressure from tiny orifices in the thinned cortex. Cyst cleaned out and packed as usual with vaseline Healed promptly and did not recur for the two years he was followed Xray Oct 10 1928 showed rapid bone repair The pathological report reads Cyst containing cholesterol crystals with a wall of connective tissue containing blood pigment (F B Mallory)

CASE XIII, C H., girl of 13 Admitted May 22, 1928 Six weeks history of swelling below the knee "size of hen's egg" X ray diagnosis bone cyst of upper tibia Other bones show no changes

Operation May 24, 1928

Cavity opened and wiped out Bone walls broken into the cavity and wound closed over blood clot.

Oct. 4, 1928 a second operation for recurrence beneath the repair scar, cleaned out and disinfected with carbolic and alcohol Packed with vaseline Six weeks later there was no x ray evidence of bone repair This never thoroughly healed, though it did not recur again as a cyst, and Sept. 11, 1933 she still had a small indolent sinus Pathologically it was reported as a cyst simply Unfortunately the only report found is illegible

This brings up the matter of other retrograde processes Broadly speaking, what becomes of giant-cell tumors? Some become cystic, as noted, and for all we know remain cystic without growth, indefinitely

Others, we have assumed, when released from tension by fracture, retrograde and are cured I know of no data for this assumption Certainly opening of the surrounding wall, in default of cleaning out, does not necessarily cure the trouble In cases operated on, and packed with vaseline, the inner surface quickly becomes clothed with granulations, the healing is by fibrous scar, much of which is presently calcified and reorganized into something approaching normal bone. The process is then over

We do not know whether fibrosis as such is one of the end results of giant-cell growth There are three cases in point

CASE XIV, P, man of 27 Seen April 26, 1932 Operated on twice elsewhere for giant cell tumor of the lower end of the femur The second time, bone grafts were put in Sepsis followed involving the knee and continued two years He showed no repair and on x ray, apart from results of sepsis, dead grafts and non union there was a definite ovoid mass, three inches in length apparently tumor, central in what was left of the shaft near the knee After a preliminary open drainage operation and some regaining of health a thigh amputation was done which healed in due normal course

To my great surprise there was no tumor as such The great ovoid mass of dense tissue within the bone was "fibrous tissue showing marked round cell infiltration There is no attempt on the part of this fibrous tissue to become calcified and no evidence of new bone formation can be made out. An occasional giant-cell is seen These giant cells have the appearance of foreign body giant cells" (J Stewart Rooney)

CASE XV, A. E., boy aged 12 Seen October 25, 1932 Fracture of left femur from two to four years previously (dates in history throughout are contradictory) Started to limp in the winter of 1931 Presented himself with picture of long mass of expansile growth in upper femur and a fresh infraction of bone wall Shows Froelich's syndrome with marked adiposity

Operation advised but not accepted He disappeared, reappeared five months later and was operated on as giant cell or cyst A fibrous tumor was found and enucleated He was put under traction as only a periosteal shell remained Under endocrine

and vitamin regimen he showed excellent repair and no sign of recurrence

June 23, 1933, a month after what seemed a normal repair by x ray there was evident a rapidly growing recurrence just below the site of the old mass

This was operated, enucleated and packed. He did well clinically and repair was progressing well, when he was taken to New York O. R. A. A. and it appears that he died there a few weeks ago at the Memorial Hospital apparently from the shock of an operation, the indications for which are not clear to us

The point of interest is that the first pathological examination by Dr Rooney showed a benign fibroma, as to which the question of metaplasia from a giant cell tumor was considered The second specimen showed growth and mitotic activity which not only Dr Rooney but Dr Leary and three other pathologists who reported, could interpret only as a malignant mass

We are not likely ever to have a conclusive answer in this case, only the sketch of which is here given

CASE XVI R D man of 27 Seen April 20 1927 Injury to leg July 11, 1926, in plaster for nine weeks followed by "refracture" and again in plaster for three more weeks and crutches to February Limp pain and sensitiveness of right hip

X ray showed a seemingly large cystic growth in the trochanteric portion of the femur Considerable expansion of bone with cortex thin and broken in two places one of which looks old (S. A. Robins)

Operation April 27, 1927 Proved to be not a cyst but fibroma Enucleated vaseline packed as usual Healed promptly treated in ambulatory splint for months to avoid deformity Bone repair complete by x ray Jan 7, 1930 Jan 8, 1931 x ray shows solid bone May, 1933, clinical examination shows a perfectly normal hip with full function

The pathological report was of "a fibroma of connective tissue consistency showing microscopically numerous spicules of bone about which there is a conspicuous proliferation of connective tissue" (L. W. Smith)

One case, pure myxoma histologically, so strongly suggests in history and pattern the giant-cell group that one is inclined to list it here

CASE XVII Mrs M S Taunton a woman of 26 Seen May 12 1933 with no history other than a twist of the right wrist (not severe) ten weeks ago Lameness persisted and thickening was noted X ray taken showed tumor cyst of lower end of radius Much disappearance of bone with the cortical layer thin and expanded the tumor extends pretty well into the radial styloid Called probable giant-cell but atypical in that absorption is very uniform and trabeculations are absent. The film shows a half healed infraction of the cortex

Operation May 14 1933 Faulkner Hospital Tourniquet applied Incision over outer side of radius and the dorsal branch of the radial nerve pushed aside No infiltration of tissue with tumor at the point where the infraction is evident. Tumor laid open and the cavity was filled with a "emulsi" paraffinlike material Cavity involving the whole diameter of the bone two inches long measuring up from the radial walls of the cavity with hard clean bone not infiltrated and with no tissue lining

Cleaned out mechanically swabbed with alcohol, packed with vaseline and boric strips Pressure dressing

Biopsy showed (frozen section) myomatous tissue without cell activity

Pathological Report "Sections microscopically through the tissue submitted for examination shows it to be composed of a very loose textured supporting stroma of fibrous tissue surrounding a purple staining homogenous material. The cells are fairly regular in outline and a very rare mitotic figure can be seen. The tissue is characteristic of a myxoma. This type of new growth must be treated as a potential malignancy. The spicules of bone submitted for examination present nothing unusual in their appearance.

Diagnosis Myxoma (Premalignant) (J Stewart Rooney)

May, 1934. This case is still sub judice, vibrating between Bloodgood and Boston

One case called probable giant-cell proved a myeloma

CASE XVIII, H. M., a man of 45. Seen April 24, 1928, with spontaneous fracture of the right humerus, high three days previously. X-ray showed a cystic picture on which no positive diagnosis was made. Operation May 18, 1928 showed a terrifically vascular tumor which was enucleated and packed. It was reported as a myeloma (Mallory). X-ray treatment was instituted.

Healing and repair went well and he returned to work continuing x-ray treatment with Dr Charles Whelan.

May 8, 1929 he was operated on at the Faulkner Hospital by me for a recurrence about the greater tuberosity.

Again the vascular tumor—but in spite of hemorrhage a more satisfactory enucleation and clean up was done. Again x-ray and rapid repair. There has been no return of the growth. Function is perfect. Examination Sept 27, 1933 showed no recurrence by x-ray. Skull negative.

The second pathological report was as follows:

Sections microscopically through the small pieces of tissue reveal the presence of numerous round and spindle-shaped cells which have somewhat the appearance of those found in sarcomas. A few giant-cells are also seen in the tissue. The new growth is characteristic of a myeloma.

Diagnosis Myeloma. (L W Smith)

April 1934. No recurrence as yet.

Another case, seen in consultation with Dr Leo Brett, was apparently a giant-cell tumor of a vertebral body, proved on operation to be myeloma, recurred, late, with cord symptoms, was again operated, and radiated, with apparent entire cure. Now reported free from trouble, years after the first onset.

These two cases, incidentally, are not unimportant as showing what can be done with myelomas.

In this connection may be cited a case of mine, years ago, that was operated on for a myeloma of the femur (with spontaneous fracture) and later for a large myeloma of a rib, and showed skull foci. He died five years from the onset of pneumonia from exposure in a blizzard.

Of interest also is the fact that very definite skull foci in that case, and small patches in the skull in case XVIII, H. M., remained stationary for a very long time. Probably one does not cure these cases but they certainly reward proper treatment and justify a certain optimism.

Some confusion may obtain between Brodie's abscess and cyst. The history may not help and

the containing wall of bone, the main diagnostic point, may show up in a cyst, and may be indeterminate in an abscess.

Now we come to cysts as cysts.

Those which most interest us are those probably without parathyroid antecedents, and that means essentially the solitary cysts single or complex, occurring typically in the shaft of long bones, with a picture (including bone expansion) practically exactly like the giant-cell masses, or else they are close to the joints in just the place for a giant-cell tumor, looking a good deal like it in the x-ray, though usually lacking the trabeculations and apt to show less penetration into corners of the bone.

Of our lists those that may with much reason be regarded as belonging to the giant-cell class, or at least related, number seventeen. These were all cases operated on and verified. So far as the data go, none recurred, none failed to repair save the unlucky case XII, and here infection may have been a factor.

But there are cases of cyst that one may not classify at all, as yet.

Case XIX, C

Case XXI, K.

Case XXII, Marble's case

Other cases must be classed as osteitis fibrosa cystica. No cases of Kohler's disease, or Kienboch's and the like are here included, though we must call them fibrous osteitis.

Of the cases that follow none were generalized, but five of the six showed other bones involved and the sixth an extension in the same bone.

Case XXIII, O

Case XXIV, R

Case XXV, H

Case XXVI, M

Case XXVII, L

Case XXVIII, G

Of these only the last has had proper lime and phosphorus study. She was referred to Albright's clinic, carefully studied and reported entirely negative. Two others had lime determinations, within normal limits, but this was a few years ago, with the technique of that time. Case XXVI is the only unoperated, unverified case.

There are a few cases not cystic at all—but obviously related.

Case XXIX, P

Case XXX, F

Case XXXI, W

There is one Case XXXII, S, the only one except Case II that can be called general skeletal involvement.

It is self-evident that many of these cases have not been studied adequately in regard to lime and phosphorus output. They antedated real modern chemistry in many cases, and are

only now being rounded up for calcium phosphorus checking, as they can be found

It is, however, pretty obvious that we have in this rough class of cases, besides the active giant-cell tumors, many cases probably related to giant cell antecedents, not generalized, that seem to range logically with the osteitis fibrosa group, about the chemistry of which we do not know

There can be no question about the value of the demonstration of lime chemistry in the type of generalized bone involvement first described by von Recklinghausen as osteitis fibrosa cystica

And it should be a matter of local pride that our researchers and surgeons have more than done their share in demonstrating that parathyroid tumors are the ultimate cause of the hyperparathyroidism of which the osteitis is one expression

Once and for all, I think we can accept parathyroid pathology as the cause of v Recklinghausen's disease and high phosphatase as the index of Paget's

But that does not quite answer the whole question of osteitis fibrosa even with cysts

v Recklinghausen's material, as I recall it, was the amazing collection of the Rokitsansky museum

The extreme type of bone degeneration and cystic change that he describes is not common with us. What we have listed as osteitis fibrosa cystica and the non-cystic forms are much more usual. How many of these cases are we going to find due to excessive parathyroid activity? Some of course, but certainly not all. Probably a reclassification is due—on these grounds. Meanwhile the clinician has his problems

Given a case which seems to be giant cell tumor or cyst—or given what seems an unclassifiable cyst, what is to be our routine? *Not waiting*, which first, leaves us in ignorance. Secondly, if we are wrong, it deprives the patient of a chance of cure of a malignant disease. Thirdly, if it is a giant-cell, waiting merely invites further involvement. Fourthly, if it is a cyst, it begs the question, for there is nothing to show that cysts disappear

Not x-ray (without operation) because first, that means x-ray treatment without diagnosis. Secondly, if the growth is already cystic it accomplishes just nothing at all. Thirdly, if it is a giant-cell tumor, x-ray may encourage its spread. There is just as good a chance of this as of the reverse*. If this occurs the end result is going to be worse than with prompt operation. Moreover, the chance of recurrence is admittedly pretty much the same and the recorded cures have often taken a long time

*It seems to be a matter of dosage. Herendeen using the massive dose technique got primary decalcification. (Herendeen R E Results in röntgen ray therapy of giant cell tumors of bone. Ann. Surg. 93 398 [Jan 1931]) Pfahler using fractional dosage has not noted this

I have just re-read Pfahler's paper of 1932† and am not impressed with the results recorded, at all

First, of course the diagnosis is often open. He states that "A biopsy is necessary only when the diagnosis remains doubtful after a thorough roentgen examination by an experienced roentgenologist." To-day, this sounds extraordinarily like nonsense. Of six cases of which skia graphs are given, one is obviously osteitis fibrosa cystica of the parathyroid type, one pretty clearly a cyst *not* cured after nearly six years, and one might be a variety of things. Of the other three, one showed prompt results, one very imperfect repair after over five years and lamentable interference with growth of the bone, and the table of 26 cases is not encouraging

Reasons against open operation are fear of a biopsy, surely not logical in face of a diagnosis of giant-cell all made, and fear of infection, which does not seem to happen with adequate technique. On the other hand, operation does as a rule bring about real repair of the tumor as well as of the easier cyst cases, pretty promptly and pretty regularly*

Much has been said about errors in diagnosis, with much criticism of pathologists' opinions. Leaving aside the vexed matter of classification of sarcomata, myelomata, Ewing's tumors, etc., and considering for the moment only the class provisionally diagnosed as either giant cell tumors or cysts, and the errors seem very few, confined in fact in our series to two x-ray mistakes, and no mistakes by the pathologist

What we wish to know is whether the tumor is malignant or not. Mostly we can get that answer, and in such shape and at such time as to be of real advantage to the patient. I am perfectly ready, this answer given, and acted on, to leave the minute classification to the research laboratory. If we can, at a serviceable time, get more from the histology, well and good, but it will decide little save as to the occasional wisdom of relying on radiation for treatment

It is time we had something like a routine. Given a tumor apparently not sarcomatous, apparently of the giant-cell or cyst class, operation is called for, promptly as a rule, and our fallibility in diagnosis demands these precautions: 1. Definite permission to deal properly with what we meet, at least to the extent of resecting a part of the bone. 2. Biopsy with a tourniquet. 3. Examination by frozen section technique (tourniquet still on). From that point on the problem is the surgeon's

So far as giant-cell tumors are concerned they may be laid open widely and cleaned out thor-

†Pfahler George E and Parry L D Treatment of giant cell bone tumors by roentgen irradiation. Am J Roentgenol 28 151 (Aug) 1933.

*Recurrences occur either way in no small proportion of the active giant-cell cases but can be reoperated with fair certainty of eventual cure

oughly from within anywhere except the spine* Cysts can be laid open wide and any lining membrane, whether of giant-cell tissue or simply fibrous, cleared from the inner wall. With the proper technique in clearing out, I am not sure of the need of corrosives to the inner surface, and they are certainly not to be used unless one is sure.

There seems to be no advantage,—and various disadvantages, to filling with bone chips or what not. Filling the cavity, after bleeding has ceased with greased gauze strips if need be, not packed in tight, gives every chance of quick repair. Dressings are seldom changed, of the same type till granulations cover the inner wall at least. Mechanical support, sometimes with traction, gives protection against fracture or collapse of the walls. Some recurrences seem unavoidable by any technique, not excepting the cases treated by radiation. There has been in my hands no death from operation, no case of osteomyelitis, only one persistent sinus. (Case H.)

There seems to be, except in spinal cases, no real reason for x-ray treatment.

One expects sound healing from within, reasonably prompt, eventually perfectly serviceable*.

For all tumors of this class may I bespeak effective teamwork of x-ray man, pathologist and surgeon. With such a team, acting together promptly, the actual clinical problem presented by this class of growths may be made almost simple†.

DISCUSSION

DR. RALPH B. OBER, Springfield, Mass. Several years ago Dr. Glickman of Springfield referred to me a Jewish woman of forty who had had a slight injury to her wrist. X-ray showed a tumor the size of a small hen's egg involving the lower end of the left radius. Under either it was found to be a soft tissue tumor rather well encapsulated.

The cavity was thoroughly cleaned out, canterized with carbolic acid and packed with iodoform gauze. It healed promptly. Recurrence occurred in a few weeks in spite of radiation.

*In cases close to joints there may be some deformity of joint surfaces—unavoidably. There may for one or another reason be less than normal range of motion as a result.

†For the moment I think the local clean up in single lesions should have precedence over investigation of endocrine function—in time.

The case was referred to Dr. Wheat, the orthopedic specialist at the Springfield Hospital. Under either he removed the lower end of the radius completely and grafted in its place the head of the fibula. No recurrence followed. The graft took nicely and to-day, four years later even by x-ray it is hard to believe that the original radius is not in place.

Both tissue examinations showed giant cell tumor. Dr. Cotton's paper offers some very interesting ideas. If nature has various ways of reacting to stimuli on the way to recovery, conservatism should be the keynote of treatment.

Should the diagnosis prove to be wrong and the condition of a more malignant nature what has operative procedure in the past proved of any more value than conservatism?

DR. E. A. JONES, Manchester, N. H. I should like to ask Dr. Cotton's opinion of this case. A man fifty-five years old had progressive swelling in the left groin for about five months. X-rays taken at this time showed a broadening of the ascending ramus of the ischium with a marked thinning of the cortex. He was given four x-ray treatments and the swelling and tenderness began to diminish, and he went on to what was called practically a complete recovery. This was four years ago and he has had no trouble since that time. The diagnosis was giant-cell tumor. This is the first one that I have ever heard of in that region until Dr. Cotton mentioned his case. I should like to ask Dr. Cotton if he would agree with the diagnosis in this case.

DR. ROBERT B. OSGOOD, Boston, Mass. I report an almost identical case to Dr. Jones which with x-ray therapy seems to show a definitely healing process which has progressed for several years.

DR. COTTON. In reply to Dr. Jones I am skeptical about these giant-cell cases that heal right up. The tumors which are really radiosensitive, if you get anywhere in these cases are likely to prove to be myelomas, but once in a while they are Ewing's tumors so-called. They are much more radiosensitive than any of the others.

The giant cell shows under x-ray one of two things, it either starts to grow at an increased rate with heavy dosages until the cortex has entirely disappeared and then the favorable cases retrograde. Those cases of retrogression show after they have retrograded about the same proportion of recurrences that you get after the operation on those cases. On the other hand if you use fractional doses of x-ray following Pfahler of Philadelphia I can't see that you accomplish much of anything. His published plates seem to me a beautiful atlas of giant cell sarcomata which probably cure themselves any way, and I think that case of yours is going to be found to be in the unfortunate class where nobody knows what it was. It might perfectly well have been a giant-cell but that is not the typical way in which a giant-cell works.

CANCER OF THE MOUTH IN WOMEN*

BY GRANTLEY WALDER TAYLOR, M D †

THE present study was undertaken with the purpose of seeking verification of certain impressions developed in the course of observation and care of women with carcinoma of the buccal mucosa at the Pondville Hospital

Briefly stated, these impressions were that there was a low incidence of cancer of the mouth in women, that there was a different regional incidence of disease in women as contrasted with men, that artificial dentures played a prominent part in the etiology, that in women the disease was relatively less malignant, progressed more slowly, formed metastases later and in fewer cases, and was relatively more curable than in men

Some measure of verification resulted from the study of results in cases of cancer of the buccal mucosa admitted to Pondville during the first two years. The series consisted of 115 cases of which 10, or 9 per cent, were women. Of the total group nine were living and well three years or more after operation, of whom three or 33 per cent were women. It was noted that seven of the ten women were edentulous, and wore dental plates. In a recent series of 83 cases studied at the Massachusetts General Hospital, eight patients were women, in five of whom there was a definite history of trauma from carious teeth or ill-fitting dentures. These findings were suggestive, although the number of cases was so small that dependable conclusions could not be drawn from the data.

A larger experience is that of the Huntington Memorial Hospital. Lund¹ has recently published several studies on the series of cases of buccal carcinoma seen at the Hospital from 1918-1926 inclusive. This series I have further analyzed by means of the punch card summaries which he prepared for his studies.

Distribution. The series consisted of 1128 cases of carcinoma of the buccal mucosa, of which 114 (10 per cent) occurred in women. When the cases are subdivided by regions, it is apparent that women have a relatively high incidence of carcinoma of the upper jaw, and a relatively low incidence of carcinoma of the floor of the mouth.

The causes of this difference in distribution must be sought in study of the etiological factors involved.

Syphilis. Lund's² study of the relation of syphilis to cancer of the buccal mucosa confirmed previous observations that syphilis is of etiological significance only in cancer of the

tongue. The contrast between the sexes in regard to the activity of this factor is very striking. Considering only those cases in which the Wassermann test was done, 25 per cent of the males with cancer of the tongue presented positive Wassermann reactions, as compared with six per cent of the females. Obviously there may have been some clinical selection of cases on whom the test was performed. But the difference between the series remains striking even

TABLE I
DISTRIBUTION

Region	Total Cases	Per Cent of Women
Tongue	409	9.3
Floor	125	4.8
Cheek	151	12.0
Palate	75	14.6
Tonsil	146	9.6
Upper jaw	67	24.0
Lower jaw	155	7.1
Total	1128	10.0

when the incidence of known positive Wassermann reactions is considered in relation to the total group of tongue carcinomas, namely 15 per cent in men as compared with 2.6 per cent in women. It may be reasonably concluded that syphilis plays a very minor rôle in cancer of the tongue in women, in contrast to its marked etiological significance in men.

Tobacco. The extremely significant etiological rôle of tobacco in buccal cancer is emphasized by this study. Data as to the use of tobacco are available in over 85 per cent of the male cases. Unfortunately less than ten per cent of the female patients were specifically questioned on this point, and they all denied the use of tobacco. While definite data are lacking for the other female cases, it is our opinion that the female group did not use tobacco to any great extent. Among the men, only 4.3 per cent were non-users of tobacco. It is probable that the relative immunity of females to cancer of the mouth is in large degree attributable to their relative freedom from the use of tobacco. The use of chewing tobacco was recorded in half the cases of cancer of the cheek (53 per cent) and lower jaw (46 per cent). Among the men the highest percentage of non-users (14 per cent) and an average percentage of use of chewing tobacco (37 per cent) occurred in cancer of the upper jaw. It is reasonable to conclude that cancer of this region is caused primarily by some other factor than the use of tobacco. For the whole group, the use of chewing tobacco was recorded in 37.3 per cent. Use of cigarettes and

snuff was recorded infrequently, and it is perhaps reasonable to conclude that they are less noxious than other forms of tobacco

Dental Status Data in regard to the teeth are unfortunately missing in nearly half the cases, and incomplete in many of the others. Certain conclusions appear reasonable from the

tively high incidence in women of cancer of the palate, upper jaw, and cheek. It is noteworthy that the male patients with carcinoma of the cheek were in a high proportion of cases edentulous, and that the use of dental plates in this group was as high as among women. In thus emphasizing the rôle of dentures, it should be

Blanks left in the table indicate that numbers were too small to justify percentage computation

data that are available (table III). It may be assumed that edentulous patients had periods of more or less protracted caries and pyorrhea before submitting to complete extractions. It is noteworthy that more women than men have complete extractions, while men keep their bad teeth longer. Women also wear artificial dentures in nearly all cases, while only about half of the men who are edentulous are provided with plates. The common use of dentures undoubtedly plays a prominent part in the rela-

understood that if they are properly used, they are probably much less dangerous than the bad teeth that they supplant. Proper use implies above all that the fit be accurate, and this in turn often requires frequent readjustments as shrinkage of the supporting structures takes place. The material should be non-irritating and of smooth surface and damaged plates should be repaired promptly. Finally, scrupulous cleanliness must be practiced at all times. In those cases in which we find cancer in asso-

ciation with the use of dentures, the plates are loose, or bring abnormal pressure to bear at certain points, or present fissures or breaks. Usually too there has been no attempt to keep the plates clean. It seems indubitable that trauma from jagged and carious teeth plays a prominent rôle in cancer of the tongue. This factor had probably been present, as I suggested above, even in those patients who were edentulous at the time of first examination in the clinic.

Degree of Malignancy When histological study is made of the grade of malignancy, it is found that a definitely larger proportion of the tumors in female cases are of low grade of malignancy.

TABLE IV
DEGREE OF MALIGNANCY

	Grade I %	Grade II %	Grade III %
Males	32	38	29
Females	44	27	29

Lund² pointed out in his study that syphilis increases the virulence of the type of growth. It is probable that the relative infrequency of syphilis as an etiological factor in the female cases may account largely for the observed difference between the sexes as regards the degrees of malignancy. When only cases with negative Wassermann reactions are considered, the more favorable distribution in female cases disappears.

TABLE V
DEGREE OF MALIGNANCY
Cases with Negative Wassermann Reaction

	Grade I %	Grade II %	Grade III %
Males	33	38	28
Females	37	29	33

If an attempt is made to analyze the degree of malignancy in relation to the region involved, the numbers of female cases become so small that reliable conclusions cannot be drawn. It is interesting, however, that half the cancers of the tongue in women were of Grade I malignancy, while only about a quarter of the male cases were in this favorable group, even considering only those with the negative Wassermann reaction.

Rapidity of Metastasis Of all the men reporting within three months of the onset of disease, 43 per cent already showed gross involvement of the cervical lymph nodes. The female cases showed only 24 per cent involvement in the same group. When the group is increased to include all cases reporting within one year

of onset, the males showed metastatic involvement in 43 per cent, and the females in 33 per cent. These figures suggest that metastasis is established early in male cases, that the percentage of male cases showing metastasis does not increase greatly with increase in time, and that buccal carcinoma metastasizes later and less often in women than in men.

TABLE VI
PRESENCE OF METASTASES

	Metastases Already Present at Examination	
	Within 3 Months	Within One Year
Males	42.7%	43.3%
Females	23.6%	32.8%

TABLE VII
5 YEAR CURES IN PRIMARY CASES
WITH NO OR SMALL NODES

	Males	Females
Failures	161	18
Cures	31	7
Inconclusive	9	2
Cures %	16	28

Cures Lund^{1, 2} showed in his study that cases which presented lymph nodes larger than about one centimeter in diameter were essentially incurable. The remaining, "potentially curable" group included 24 per cent of the female cases, and slightly less than 20 per cent of the males. Cures in this group are shown in table VII. It will be seen that for the group the cures in women are 28 per cent, while the cures in men are only 16 per cent. Although the series is small, the difference is so marked as to be suggestive.

SUMMARY AND CONCLUSIONS

Cancer of the buccal mucosa is rare in women as compared with men. Cancer of the upper jaw is relatively more common in women than in men, and cancer of the floor of the mouth is relatively less common.

Syphilis is a less conspicuous etiological factor in women than in men in relation to carcinoma of the tongue.

The almost universal use of tobacco among men may account in large measure for the greater incidence of cancer of the mouth in men than in women. Among the men chewing tobacco is especially prevalent in cases of cancer of the cheek and lower jaw. Tobacco seems to be of least etiological significance in cancer of the upper jaw.

Bad teeth are a very conspicuous etiological factor for the whole group. Men cling to bad teeth longer than women, while the latter have earlier extractions and much more often provide

themselves with dental plates. Improper use of dental plates undoubtedly plays a prominent part in the etiology of cancer of the mouth in women and perhaps of cancer of the cheek in men.

Men in general have tumors pathologically of higher grade of malignancy than women. This is largely due to the influence of syphilis in increasing the grade of malignancy.

Cancer of the buccal mucosa appears to metas-

tasize earlier in men than in women and more frequently.

The prognosis for five-year cure of cancer of the buccal mucosa appears to be better in women than in men.

DIAPHRAGMATIC HERNIA*

Medical and Surgical Treatment

BY S ALLEN WILKINSON, M D †

THIS report concerns itself chiefly with the medical handling of the smaller varieties of diaphragmatic hernia and a discussion of the symptomatology arising from its presence. Before the advent of roentgenography, hernia of the abdominal organs through the diaphragm was recognized chiefly at the autopsy table and was thought to be a comparatively rare condition occurring only after severe crushing injuries or from congenital defects in the diaphragm. With the increasing frequency of x-ray examinations, it is now generally accepted that diaphragmatic hernia is by no means an infrequent finding. In 1912 Griffin¹ collected 650 cases from the literature and his own practice of which the diagnosis had been made clinically in only fifteen. Morrison² reported forty-two cases in 3 500 gastric cases studied, a ratio of one to eighty-five. Carman and Fineman³ in 1924 reported a ratio of one case in 18 000 for patients of all types, but this figure is unquestionably much too low. In the series reported in this paper the ratio is one to 477, including all cases coming to the Lahey Clinic during the period covered by this study.

With improvement in roentgenologic technic, it was to be expected that the proportion of cases discovered would increase and for a similar reason it is to be expected that diaphragmatic hernias would be discovered in a much earlier stage than those which caused symptoms demanding operation or which resulted in the death of the individual. The cases summarized here illustrate this fact, for it will be seen that only a small number required surgical intervention or caused the death of the patient, while most of them were readily amenable to treatment and a few caused no symptoms of any kind.

The cases summarized here were treated in the last seven years at the Lahey Clinic and represent all grades of hernia through the diaphragm from a tiny protrusion of the stomach

to openings large enough to allow whole organs to pass into the thorax, but most are illustrative of the ordinary herniation found in the course of the routine gastro-intestinal examination.

An outstanding feature in the group was the difficulty in making even a provisional diagnosis of the condition in the vast majority of cases from clinical observations alone. There is no syndrome or symptom complex that is definitely diagnostic although it will be shown that a number of symptoms are very constant findings. The one condition which is most commonly diagnosed provisionally is peptic ulcer and in this series of seventy cases there were forty where this was the tentative diagnosis. Yet, in only ten cases was ulcer found.

TABLE I

DIAPHRAGMATIC HERNIA

Symptoms

Frequency of Occurrence

	Cases
1 Postprandial pain or distress	47
2 Night pain	40
3 Relief by alkalis	37
4 Vomiting	33
5 Substernal pain or lump	15
6 Upper abdominal pain not periodic	14
7 Gas and belching	12
8 Heart burn	10
9 Dysphagia	4
10 Hiccough	2

The variability of symptoms is illustrated in table I. Naturally most of the cases had more than one symptom, but in some the symptoms were very mild or were masked by complaints referable to associated conditions. In only four cases of this series were there no symptoms which might be connected in any way with the presence of the hernia through the diaphragm. It is noteworthy that the four most prominent symptoms listed in order of frequency are all outstanding symptoms of peptic ulcer. The remaining symptoms listed are found in many conditions both functional and organic, involving the whole digestive tract.

From the Gastro-Enterological Department of the Lahey Clinic.

It will be seen that for the group the cures in women are 28 per cent, while the cures in men are only 16 per cent. Although the series is small, the difference is so marked as to be suggestive.

SUMMARY AND CONCLUSIONS

Cancer of the buccal mucosa is rare in women as compared with men. Cancer of the upper jaw is relatively more common in women than in men, and cancer of the floor of the mouth is relatively less common.

Syphilis is a less conspicuous etiological factor in women than in men, in relation to carcinoma of the tongue.

The almost universal use of tobacco among men may account in large measure for the greater incidence of cancer of the mouth in men than in women. Among the men chewing tobacco is especially prevalent in cases of cancer of the cheek and lower jaw. Tobacco seems to be of least etiological significance in cancer of the upper jaw.

Bad teeth are a very conspicuous etiological factor for the whole group. Men cling to bad teeth longer than women, while the latter have earlier extractions and much more often provide

covered in younger individuals, whereas the average age is fifty-four years (table V)

The very fact that the diagnosis is almost always made solely by use of the roentgen ray carries with it the corollary that the roentgen ray should be used whenever the diagnosis of diaphragmatic hernia might be a possibility. Because the majority of these hernias cause no

obstruction, it is usually impossible to visualize them by fluoroscopy in the erect position, but practically all can be seen if the table is flat or in the Trendelenburg position. As a rule the hernia is easier to visualize by fluoroscopy than by films for the reason that it may not remain above the diaphragm or may not remain filled during the entire time of the observation. In some cases it fills only if the patient is turned rapidly to one side or the other.

Symptomatically a small diaphragmatic hernia must be differentiated from peptic ulcer, gall bladder disease, reflex disturbances of the stomach due to irritable colon, and simple hyperchlorhydria. Large hernias are more apt to cause obstructive symptoms or disturbances in the chest, such as dyspnea, substernal pain, heart pain, or dysphagia. Roentgenologically the smaller variety must be differentiated from cardiospasm with a dilated esophagus and cardioesophageal relaxation, to which Robins and Jankelson⁹ have called attention. The large hernias may, paradoxically, be more difficult to diagnose than the smaller type. LeWald has pointed out that thoracic stomach is similar in appearance, but there is no hernia, the esophagus is short, and the pylorus passes through the diaphragm. Eventration of the diaphragm simulates hernia, but the stomach is entirely below a very high diaphragm. Roentgenograms of the chest may show a gas bubble or fluid level simulating pneumothorax or hydrothorax.

The surgical treatment of diaphragmatic hernia has many advocates including Harrington¹⁰, Woolsey¹¹, Truesdale¹², and others, but these writers are referring to the large hernias where the organs concerned are chiefly above the diaphragm. On the other hand, most of the hernias in this series are small enough not to produce symptoms demanding operation, and they are usually controlled by medical measures. The

keynote of medical treatment has been indicated by Sara M. Jordan¹³, who has stressed the importance of functional tranquility in the treatment of abnormal mechanisms. In that sense the treatment here is largely symptomatic. It is of the utmost importance to treat and correct the associated conditions, whether functional or organic. If an ulcer be present the usual treatment is instituted and as the ulcer symptoms are relieved, the hernia ceases to be troublesome. Irritable or unstable colon is so often present that it must be treated, and in most cases other forms of treatment are ineffective until the bowel is performing normally. It is striking to watch the improvement and disappearance of a patient's complaints of heartburn, substernal distress and pain after eating

TABLE VI
DIAPHRAGMATIC HERNIA

Medical Treatment

by the simple correction of a disturbed bowel function and the institution of a bland diet. Table VI indicates the types of medical treatments used. It will be noted that twenty-six cases, or 50 per cent of those treated medically, had some form of ulcer treatment, although the formal Sippy diet was followed in only fourteen cases. The other cases so treated were those with a high acid who failed to respond to a simpler form of treatment. If a hyperacidity is found, it will usually be necessary to correct this by the administration of alkalis. One point of interest is that these cases tolerate magnesia poorly. Magnesia stimulates the colon to overactive peristalsis and increases spasm in the already irritable bowel which is such a common finding in these people. This, in turn, reflexly disturbs gastric motility, and distress is increased instead of relieved. If constipation exists it is preferable to control it by dietary measures combined with antispasmodics rather than by any form of laxative.

Table VII indicates the methods of treatment used in the surgical cases. This group includes two cases that were medical failures. It is noteworthy that one of the cases with an abdominal

Since there is no characteristic clinical symptom complex, the diagnosis can only be suspected at best, and in those instances where the hernia is composed of a fraction of the cardiac end of the stomach, it will usually be missed, even as a tentative diagnosis. Harrington states that "the symptoms of diaphragmatic hernia are probably more commonly confused with those of cholecystic disease than with any other lesion of the upper part of the abdomen." In Morrison's² series the clinical diagnosis was ulcer or gall stones in practically all cases. Bevan⁴ made the same observation in 1920, and Richardson⁵ in 1929 calls attention to the same fact.

While it is true that the larger, more severe grades of herniation of the stomach or other organs through the diaphragm can and do simulate gall bladder disease, it seems that this phase has been unduly stressed, while the simulation of gastric or duodenal ulcer by the much more common, small hernia of the stomach through the esophageal hiatus has not received the attention it deserves. In this series, the contents of the hernia consisted of the stomach only in sixty-seven cases, and in forty (60%) of these the tentative diagnosis was peptic ulcer. If the symptoms so strongly suggest peptic ulcer in 60% of cases, it follows that somewhat similar conditions must be operative, and that, whenever a diaphragmatic hernia of the stomach is present, the development of symptoms simulating ulcer would be more apt to occur than any other symptom complex.

TABLE II
DIAPHRAGMATIC HERNIA

Associated Diseases

Disease	Cases

Diverticulosis	16
Ulcer, peptic or esophageal	10
Cholelithiasis	8
Hernia elsewhere	6
Cirrhosis of liver	2
Carcinoma of colon	1
Acute appendicitis	1

Diaphragmatic hernia, particularly the lesser gradations of it, may be the only organic lesion found, but there is usually some associated functional condition which often overshadows the picture. The most frequent of these is irritable or unstable colon in 55 per cent of cases (table II). Chiefly because they are common in the same age group, diverticulosis occurs in 23 per cent and gall stones in 14 per cent of the cases respectively. The findings in this group of cases have impressed us strongly with the necessity for a complete gastro-intestinal study in all cases presenting symptoms referable to the alimentary tract.

The observation has been made that many cases of herniation of the stomach through the

diaphragm develop an ulcer in the hernia. Mathews and MacFee⁶ have reported a series of such cases. Harrington states that hemorrhage from gastric erosion at the site of the esophageal hiatus produces ulcer. There were ten cases of ulcer in this series (table III) of which only three had any direct relationship to the hernia. One of these was visualized by esophagoscopy and later caused the death of the patient by

hemorrhage. There were six duodenal ulcers and one gastric ulcer, all of which should be regarded as coincidental findings rather than as results of the hernia.

TABLE IV
DIAPHRAGMATIC HERNIA

Size of Hernia

% of Stomach Above Diaphragm	No of Cases
10%	20
15%	21
20%	12
25%	9
33%	3
50%	2
100%	1

Since these observations concern chiefly small hernias, it is of some interest that 79 per cent of our gastric hernias were estimated roentgenologically to contain 20 per cent or less of the stomach (table IV). This fact also explains why the symptoms arising from these hernias are relatively mild and why they differ from the symptoms ascribed to hernia in many of the earlier writings. In most of the articles the cases reported were extensive, and the pathological conditions found were much more involved than in most of our own. Harrington⁷, LeWald⁸, Morrison², Richardson⁵, and others have called attention to the short esophagus in most of these cases. The majority of the cases reported here are of this type. The esophagus enters the top of the hernia and appears definitely shortened. It seems probable that most of these are of congenital origin, but it is unlikely that the defect has always been present. If this were true more hernias should be dis-

CHRONIC ARTHRITIS AND ITS TREATMENT*

BY H ARCHIBALD NISSEN, M D †

INTELLIGENT discussion of any significant problem provokes innumerable questions. Discussion of arthritis invariably revolves about questions concerning safe, efficacious analgesics for relief of pain, the value of vaccine and intravenous drug therapy, the classification of arthritis by type, the reason for contradictory results of the same treatment applied to individuals apparently showing the same type and extent of arthritis, the different individual reactions to infection, allergy, and diet.

Twenty-four years ago Nichols and Richardson¹ in an article on arthritis wrote

"Conclusions 1 In non-tubercular deforming arthritis there are two pathological types of joint changes (1) the proliferative type which tends to destroy joint cartilage and leads to ankylosis of adjacent joint surfaces and (2) the degenerative type which tends to destroy the joint cartilage and produce deformity without ankylosis

"2 These two types do not correspond to two definite diseases but each type represents reaction of the joint tissues to considerable variety of causes

"3 In neither type if the original injury is sufficiently severe, or if the causative factor continues to act, is there likelihood of regeneration of a perfect joint

"4 A joint injury of a sufficient degree even if the primary cause ceases to act, may of itself continue to act in a vicious circle as a cause of continued joint change

"5 Clinically the aim should be to recognize the type and stage of lesion present and then to determine and remove the active cause

"6 The prognosis should be guarded because of the difficulty in determining the active cause because of the unlikelihood of complete regeneration of a severely injured joint and because of the known clinical history of many of the cases"

Since 1909 progress has been made regarding the general conception and care of arthritis and in recent years an increasing interest in the subject has arisen, but the actual etiology of the disease and the prognosis of the individual case remain uncertain. Solution of these problems lies in two contemporary lines of research,—laboratory and clinical. To the scientist in the laboratory falls the study of the disease *arthritis* to the clinician in practice, the study of the *individual* who has joint impairment or arthritis. One is dependent on the other and each is equal in importance. This paper presents the point of view of the clinician, and emphasizes the therapeutic value of the psychiatric approach to the arthritic patient.

Accepting the truth of Nichols and Richardson's statement, arthritis is *one* disease, varying in the individual in different decades, in different occupations, and with different response to infections. (In any number of instances serial radiograms showing both degenerative and proliferative changes in the same patient offer proof of this.) Therefore *individualistic reaction* being the single generally recognized factor in the arthritic problem logic points to the *individual* as the center of concerted study. The first requisite of treatment of the individual is study of the entire body and recognition of all the mental and physical defects. The only way to recognize the physical defects is by most careful and thorough examination and inclusive radiographic and laboratory tests all repeated at regular intervals. The only way to recognize the mental components of the picture is by gaining the patient's complete confidence and thereby gradually learning the real self of the individual his joys and sorrows.

The body is a beautifully balanced piece of machinery and as in the case of any machine, difficulty in one part inevitably causes difficulty in other parts. Once the perfect balance, homeostasis as Cannon² calls it, is destroyed dysfunction small or great in one after another of the various systems which go to make the whole follows. The first, tiny break in the machine's perfect mechanism may be no more

repair has since had a recurrence of the hernia, but is having no symptoms of it

Paralysis of the diaphragm by phrenic exeresis offers a theoretically ideal method of treatment in many hernias where the symptoms persist after adequate medical trial. It prevents motion and consequent pinching by the diaphragm of an incarcerated hernia. Because the diaphragm rises, the hernia may reduce itself in some instances. The cessation of diaphragmatic motion prevents any tendency to pump the contents of the stomach from a region of positive pressure below the diaphragm to a region of negative pressure in the thorax. Practically it has offered a definite cure for the dis-

In table VIII are listed the deaths that have occurred in this series. One was caused by hemorrhage from an esophageal ulcer, from disease presumably unrelated to the diaphragmatic hernia, and two from operative procedures. One of these cases was moribund on admission and had only a phrenicotomy and a jejunostomy in an attempt to relieve a high obstruction. The hernia contained stomach and small intestine. The other case died of postoperative pneumonia.

SUMMARY

Of seventy cases, sixteen males and fifty-four females, there were forty in whom the symptoms suggested peptic ulcer more than any other

7	No	Stomach	Abdominal repair	Recurrence, no symptoms	—

treating attacks of hiccoughing to which some of these cases are subject, and in the few cases of this series where it was used, it relieved pain and substernal distress as well. Some of the

gastro-intestinal condition. In ten of these, an actual ulcer was demonstrated.

The diagnosis of diaphragmatic hernia is almost solely a roentgenologic diagnosis. Frequently a special technic is necessary to demonstrate the lesion when it is present.

Associated gastro-intestinal complications are common, and may produce the only symptoms of which the patient complains.

Successful medical treatment must be directed at the associated conditions rather than the hernia itself in nearly all instances. Medical treatment is preferable to surgery in most small hernias.

Surgical treatment should be reserved for those cases where medical treatment fails to control the symptoms, and the size of the herniation is not of itself a reliable guide in deciding for or against surgery.

A phrenicotomy is advised as a preliminary to more extensive procedures, and it, alone, may relieve the condition.

TABLE VIII
DEATHS

- 1 Postoperative intestinal obstruction
- 2 Postoperative pneumonia
- 3 Hemorrhage from esophageal ulcer 7 months after medical treatment.
- 4 Carcinoma of liver 5 months after treatment. Location of primary lesion unknown.
- 5 Heart failure 6 months after treatment. No symptoms of hernia after treatment.

large hernias require no surgical intervention. In particular, extensive surgery is contraindicated if the esophagus is short and there is no obstruction. In the short esophagus type with a large part of the stomach above the diaphragm, torsion may occur resulting in obstruction. Here phrenicotomy or phrenic exeresis may offer a simple, safe and immediate relief, whereas operative repair of the defect is impracticable.

pus oozing from the sockets, and no arthritis be present. Another may show a chronic middle ear disease (which means actually reinfection from time to time), tuberculosis, active or inactive, chronic cystitis with pyelonephritis above, or may actually demonstrate after death a variety of focal or generalized infections though he showed no demonstrable arthritis during life. In other words, it is the individual's reaction to infection rather than infection in the individual that is important. Arthritics who have infections present may be reacting to a protein, either exogenous or endogenous. The presence of bacteria in the tissues with no immediate response, functional or pathological change in the joints, indicates the type of tissue (or soil) resistant to, or able to carry, this extra load, whatever protein irritant or unknown irritant may be present in the body. Then *what* changes the tissue resistance to these extra loads, so that it fails to hold them in check, or to render them harmless in the body? Does the answer not lie in general disorder of the homeostasis, and is the response of the body to infection, toxemia or bacteria not due to the homeostatic imbalance rather than to the actual agents *per se*?

Whereas no one constant etiological cause of arthritis has yet been found, twenty-two or more common factors have been noted in different patients in varying numbers just previous to the development of arthritis. Whether one or more of these factors may be the extra straw that turns one individual into an arthritic, another into a schizophrenic, and a third into some other type of chronic disease syndrome is not known. Study of arthritis along lines similar to those being used in dementia praecox may bring the answer nearer, if attention is directed to the *individual reaction* rather than to any specific agent producing the arthritic process.

Systemic involvement is found in the arthritic irrespective of age or known duration of the arthritis. Changes which involve every portion of the body are noted in different individuals. The very multiplicity of functional disturbances points definitely to the conclusion that there may be no one etiological agent in arthritis, but that the process may follow psycho-physio-chemical changes, in some instances developing upon poor tissue inheritance, in some precipitated by the extra load of bacterial invasion or allergic reaction, but in many the vicious psycho-physio-chemical cycle starts first in the psychical life of the patient after years of inner conflict, maladjustment to environment, thwarted hopes and desires, or nervous shock and strain. A review of the life histories of a group of arthritics shows in many, emotional instability unfulfilled ambition, defeating drudgery of life, sufficient to account for the initial disturbance of the endocrinal system. Endocrine dysfunction may alter the function of the gastrointestinal

tract, the cardiocirculatory system, the liver, the kidneys, or the involuntary nervous system, with ensuing or coincidental joint changes. Many have lived for years preceding the joint manifestations with inner conflicts, unexpressed rebellion against life as it was meted out to them, work when they wanted schooling; repeated, unwished-for child bearing, longing for the big things in life when obviously the little things must be that individual's portion, in short, there is more than sufficient background to produce a body revolt, either cataclysmic, or slow, insidious and progressive.

A reasonable hypothesis arises at this point. If one accepts the broad separation of peoples into introverts and extroverts, may it not be that the introvert reacts to overwhelming odds by a psychopathological response whereas the extrovert obtains the same relief from responsibility through a joint, or arthritic, reaction? Comparison of the dementia praecox, or schizophrenic, patient with the arthritic brings out interesting points of similarity, the difference being the outlet thrust upon the individual. In one, dysfunction of the personality predominates; in the other, dysfunction of the bone and joint furnishes an unrecognized alibi for withdrawal from active life, or a means, through capitalizing disability, of gaining attention which had been previously unobtainable. From the broad biological point of view all such reactions must be regarded as fundamentally purposive.

Hoskins³ has written on the "Schizophrenia Problem from the Standpoint of the Investigator." With a few changes and a few additions, the etiologic factors listed by Hoskins as potentially important in the schizophrenic might well be transposed for those of the arthritic. He lists: Emotional conflicts. Withdrawal of interest in environment and transfer to phantasy life. Bad mental and physical habits. Industrial and social maladjustment. Structural defects of body. Defective brain metabolism. Abnormal endocrine function. Autonomic nervous dysfunction. Cardiovascular insufficiency. Defective gastrointestinal functions. Liver dysfunctions. Abnormal mineral metabolism. Disturbed acid-base equilibrium. Vitamin deficiency. Infectious and surgical disease. Other metabolic disease.

SUMMARY

This view of the arthritic problem may be repeated in one sentence. *Study and know your patient thoroughly from every avenue of approach.* If the physician develops a scientific type of mind, the emotional checkreins will not hinder him from attempting to obtain every bit of information possible about a patient. With this as a basis, a practical outline of living may then be built. The patient's problems cannot be dismissed by saying, forget it, or we won't dis-

than slight environmental maladjustment, domestic friction, or seemingly minor worry. The continuance, however, for any length of time of such mental disturbance may soon be followed by signs of slight imperfections elsewhere in the body. This means that regardless of the particular thing of which the patient complains, joint, heart, or kidney, the first step is to study the patient as an individual, his body in its entirety, his physiology and chemistry, his mind and mental outlook on life, his emotional reactions, his family inheritance, his early environment. The combination of all these factors makes for the physical changes present in the arthritic, who shows a definite psycho-physio-chemical reaction to an unknown quantity X as the original excitor. The important influence on normal body physiology of mental or psychical reaction is well known. In abnormal physiology it naturally assumes greater bearing. For instance, in a diabetic following his routine and practically sugar free, extra fatigue plus a tremendous emotional crisis may precipitate a typical sugar storm. Minor physical reactions to emotional stimulus, such as blushing, tachycardia, or blanching of the fingers, are common occurrences. As the insidious physiologic dysfunctions occur in a potential arthritic, the joint in turn may be affected.

Prolonged work with arthritic patients emphasizes two particular points: first, the fact that the joint involvement is in almost every case but one manifestation of general body dysfunction, with and without actual pathological change (few arthritics show normal function of the entire body), secondly, the fact that *time and patience* are essential in the successful treatment of the chronic case. They are essential, first, in gaining the necessary knowledge of the individual patient through the study of his physical and psychical make-up, and secondly, they are equally essential in making practical use of this knowledge when gained.

The different signs and manifestations of arthritis seen in general practice are too familiar to need detailed description. In the sorry pageant is the individual with repeated mild flare-ups of pains, with tissue congestion but no bone or joint change, the one with moderate intermittent disability and pain, mechanical in origin, due to lipping and spurring of bone in back, hip or knee. Among these is the patient who has probably had degenerative bone and joint change present for a short or long time but has not had symptomatic knowledge of such change. Radiograms of so called normals have shown this to be correct. If an individual is one of this group, in any decade, activating factors such as exposure to inclement weather, occupational hazards, various infectious irritants, exogenous and endogenous, endocrinal disturb-

ances, or psychogenic imbalance, may precipitate the onset, or produce recurrent flare ups, of symptoms and signs in already damaged joints. Experience teaches that there is a *natural* duration of such attacks. The average length of an attack, or flare-up, is from six weeks to a few months. Then there is the patient with a single stiff joint, the one with rigid spine, or with spine and hips involved, and finally the one with multiple joint destruction and deformity with associated skin and muscle change. Duration of arthritis does not appear to indicate which one of these courses will be taken, nor is it sufficient in itself to suggest what to expect in the future.

These different final arthritic stages are easily recognized. What is necessary to successful treatment is the ability to foresee, and if possible forestall, the patient's future course when the first vague, or acute, symptoms appear. This again requires detailed knowledge of the patient, through his first few years of life to the moment the physician sees him. Repeated visits and conversations between patient and doctor are required to learn the real life story, the family relationships, early environment, early nutrition, educational opportunity, past history, present illness, and most difficult and most important, the inner self of the patient, his emotional, nervous and mental adjustment, or maladjustment, to life. It is not easy to secure an accurate history from a chronic patient. The first history taken tells none of these things. An initial statement of "No history of shock or worry" is usually disproved after repeated visits and friendly talks between the physician and patient, when confidence and faith have been established, and the self-protective walls the patient has built up have been allowed to disintegrate. This is one reason why the physician must put in ten or fifteen years of apprenticeship with a definite group of patients, and follow them closely, in order to draw accurate conclusions in chronic disease.

ETIOLOGY

As regards etiology of arthritis, undoubtedly heredity plays a part, not necessarily an arthritic inheritance, but the constitutional inheritance, the mental and tissue characteristics to which the individual falls heir. The early absorbed motivations for later living and the nutritional program followed for the first years of life, especially the first, are important. Infection, in some cases particularly, is the definite, additional load which hastens the onset of arthritic manifestations. The arthritic syndrome may appear whether the probable focus of infection is left in the body or is removed. One individual may have a definite endocarditic septicemia or bacteremia and not show any joint involvement. One may show infected teeth, with

should again be attempted as the signs of over-fatigue subside. Massage has definite measurable subjective and objective value if given by a competent physiotherapist. Heat in any form which is most comforting to the patient is useful.

ALLEVIATION OF PAIN

The patient consciously wants two things—relief and freedom from pain and avoidance of future crippling. (Unwittingly he may want what he practically always needs—mental and emotional outlet and rehabilitation.) Opiates take first place for relief of pain. Any analgesic which is effective in alleviating pain in an individual patient is the one to use for that patient, provided it has been proved harmless. The dosage of any drug should be that sufficient to produce the desired pharmacological effect. If more opiates were used to relieve pain possibly less joint deformity would occur in the arthritic, particularly if used during the acute stages of the disease when the one desire is to find a comfortable position for an aching joint or during the time that corrective plaster casts are first applied. This new and sometimes uncomfortable or painful position of a joint necessary in corrective and preventive work, will be better tolerated by the patient and will be maintained for longer periods if sufficient medication is administered to obliterate the ache. Obviously the administration of sedatives and analgesics demands good judgment and experience on the physician's part.

VACCINE THERAPY

There may be a certain amount of improvement obtained in some arthritides through vaccine therapy. However, one must remember that this vaccine therapy is not specific or at least has not been so proved conclusively to date nor has it been proved more beneficial than oral medication. In gauging the efficacy of any treatment one should bear in mind the average duration of the usual joint flare-up from the time of its onset to the time of its subsidence. The result of a specified treatment should be tested to see if this expected period of relapse has been shortened, if the interval period of remission has been lengthened, or if the frequency of relapse has been decreased. As a rule the best results of vaccine and intravenous drug therapy occur in the so-called mixed type of arthritis where to underlying hypertrophic or degenerative changes with no joint symptoms has been added irritation resulting from reaction to infection strain fatigue etc. Such a combination is apt to run its course whichever irritant is present and at the end of the flare-up the joints usually resume practically their former function. Six weeks to three months seems to be the average duration of such a flare-

up if it is due to one application of a single excitant. On the other hand, if the preexisting, inactive degenerative changes are transformed into an active arthritis by multiple, or repeated irritants the definite period of flare-up is lengthened and may become a permanent condition with progressive joint involvement. If vaccine or intravenous therapy is used in this type of individual and improvement is noted at the end of say sixteen injections given at weekly intervals the physician may well question whether his treatment per se caused this improvement.

However if real benefit to the patient by vaccine therapy is proved the results must be related in some way to the protein introduced into the body and the body's reaction to it which for want of a better term we may call allergic response to a protein. In other words an element is introduced which the body's normal autonomic system does not handle without producing certain changes elsewhere in the body. Desensitization means the introduction over a fairly long period of time of certain substances which are irritants. Even when this desensitization has diminished the sensitivity of a joint, the arthritic element is not altered. Pain may be abolished and greater functional range of activity may be obtained but actual joint change, if present remains constant. It has been suggested by some writers⁵ that minor allergic reaction or positive sensitiveness to certain proteins may vary from month to month. If this is so it seems more reasonable to use what is known to be harmless such as milk or peptone, or milk protein than to use actual vaccine of suspended dead bacteria in saline solution or mixtures of antigens which at times produce a disagreeable systemic reaction.

DIET

Dietary information is sometimes difficult to obtain from the patient. This is made more accurate if he is asked to keep a daily record of the actual food and liquid ingested, and such records over a few weeks' time are studied. In the matter of diet the points to be remembered are attractive preparation and serving of the food as well as its fundamental wholesomeness. The quantity given should be that which will give adequate nourishment to the individual involved. As there is no one drug for arthritis so there is no one diet for all arthritic patients. However the accepted diabetic diet seems a good basis on which to build the individual arthritic diet. Modifications are necessary. In one patient the protein should be increased in another the carbohydrate should be decreased depending on that individual's ability to handle sugar and utilize it in whatever form it is given. In others it is well to reduce the cholesterol intake because of its uncertain

cuss the matter, if it happens to be an unpleasant sex incident, or even by the mere recognition of the problem without offering a practical solution. Never pry into a patient's inner soul and mind, and, because you are at a loss for a remedy, leave him stripped bare. Do not use psychotherapy at all unless prepared to carry through to a solution each contingency as it may arise. The general practitioner, or internist, must take the time with each patient to obtain this history in detail, he must know the man or woman as a human being, must know his background, his early environmental influence. He must gain the patient's confidence, and this requires patience, until that individual knows he has found that for which practically every chronic disease patient actually yearns, i.e. some one genuinely interested in himself, his trivial signs, symptoms and problems. This means of course unhurried talks frequently repeated. However, since the chronic, whether his immediate problem be joints, heart or other system, almost invariably shows dysfunction of several body systems, it is evident that such multiple change requires the knowledge and help of as many specialists as there are fields involved. Equally evident is the fact that each specialist tends to see the patient in the light of his own specialty, and unconsciously emphasizes that part of the body. The internist's job is that of liaison officer, or pilot. He must see the patient as an entity, and must keep the balance, so that undue emphasis is not placed on any one part to the neglect of another.

TREATMENT

Treatment of the arthritic first and always must be recognized as individualistic, not from the point of view of the physician prescribing treatment but from the point of view of the patient receiving it. The altered function of the many different body systems shown in each individual patient makes it obvious that no one drug, no one form of treatment, can be omnipotent to stimulate and restore to normal all the various systems involved.

Certain measures are practical and of definite value. Their value to the patient's immediate relief is possibly indirect, but still definite, their primary importance is to aid in arriving at an early diagnosis. There are serial tests of various kinds, adequate and comprehensive enough to enable the physician to differentiate functional and pathological signs and symptoms, and to determine accurately the time at which pathological change may supervene on previous functional abnormality. So many of the complaints of the chronic patient have been found to be due to functional disturbance of a particular system that the danger becomes real of overlooking changes which may not be functional. No symptom or sign should be considered as merely functional until pathological change

has been absolutely ruled out. Such serial studies should include radiograms, not only of joints, but of the skull, brain, chest and gastrointestinal tract, as well as the genito urinary tract when indicated. Serial radiograms demonstrate the development of sclerotic changes. After radiographic technique has been standardized vascular changes may be recognized before calcification of the vessels has become actual, and in time prevention of such calcification may be possible.

The blood count should be checked at six month intervals at the longest. Chronic arthritides show a definite tendency to anemias. Certain blood chemical determinations, such as sugar tolerance, cholesterol, nitrogen metabolism and sedimentation rate should be made and repeated periodically. Kidney function should be further tested by frequently repeated urinalyses, by phthalein tests, and by the concentration and dilution test.

Photographs of the patient in the nude record year by year the changes, whether for better or worse in posture, motion and deformity of the joints. Such photographic records are bound to be more accurate than verbal description. (Their accuracy depends naturally on the way the photograph is taken. For instance, if measurement of permanent flexion deformity of a knee is desired, the patient must be lying on a firm surface, not on a soft, yielding mattress, when the photograph is taken.)

All these tests or measurements, repeated at regular intervals, will help to clarify many existing impressions, and may shift them from the column labeled *impressions* to one labeled *facts* in the ledger of clinical medicine.

SUPPORTIVE MEASURES

Supportive, stimulative treatments are very essential. One of the first of these is *rest*, general and local. A precise presentation recognizing the value of rest to relieve pain was written years ago by Hilton.⁶ Today this fact is still appreciated. If one single remedial agent in the treatment of arthritis were to be chosen, *rest* would certainly be the one selected. Routine rest periods must be prescribed and planned as any other form of treatment. Two forms of rest have been mentioned, general and local. There is a third, *rest of mind*. Often rest of mind is secured only by genuine psychotherapy.

Exercises, also general and local, supervised, and sufficient to increase the tone of the muscular system, are equally important. Voluntary daily movement of each joint for a few minutes should be a part of the daily routine. The number of the exercise periods and their duration depend upon the individual's reaction. Increase in pain, muscle tremor, trembling shivering, etc., after a few such motions indicates less frequent and shorter periods, gradual increase

Course A. If several operations were required for reconstruction it seemed that the interval between should be at least one year

PSYCHOTHERAPY

Psychotherapy has been left to the last because special emphasis is laid upon it. It is the treatment which should be instituted first from the moment of contact between doctor and patient, running parallel to all other forms of treatment used. The better the understanding developed between the physician and patient, particularly the chronic patient the better the result obtained. So often one finds in the discharge note of a chronic patient the words "Discharged against advice", "Discharged because of lack of cooperation", "Refused treatment", etc. Doubtless all these accusations are true, but do they not reflect on the physician as well as the patient? Do they not represent but another factor accompanying the make-up of the "chronic", another systemic dysfunction needing treatment? Is not the mere fact of such summary dismissal from a hospital ward, because of one of these charges, admission of failure on the doctor's part? Does it not indicate ignorance of, or failure to deal successfully with, problems of behaviour and psychoses of varying degrees? If for no other reason than this, one cannot emphasize too strongly the value of greater study and practical use of such psychotherapeutic measures ready at hand to the average practitioner of medicine. The former family doctor had not the advantage of much of our present-day knowledge, but he was ahead of us in the matter of thorough intimate understanding of his patient.

Of what use is it to cure a body if a mind is left ill? Certainly it is not enough to arrest or cure body disease if the motivation for living is ignored. Psychotherapy is stressed because in many arthritides, particularly in the so called rheumatoid, or the patient showing proliferative joint changes, the physiochemical changes in the body appear to follow psychical changes, endocrinal dysfunction ensues, and subsequently the body systems so controlled are affected insidiously. Hence if one undertakes the treatment of chronic disease he must be prepared to give the time and patience necessary to this form of treatment.

CONCLUSION

Outstanding important points emphasized in this paper, which heretofore have not been stressed sufficiently, are the following:

- 1 The possibilities for research offered to the medical profession in the arthritic field along both laboratory and clinical lines. Clinical study, such as is here presented, emphasizes the need of long-time observation of the same group of patients before accurate conclusions can be drawn. Conclusions drawn from a

composite picture made up of segments culled from different groups of patients in different decades and at different stages of disease can never be accurate.

- 2 Rest is the single outstanding therapeutic agent whose value is accepted by all. Physical and mental rest and relaxation are interdependent and are of equal importance.
- 3 Successful treatment of arthritis demands measures to relieve pain. In addition to humane considerations, the relief of pain is of primary importance because it breaks into the vicious circle by which the arthritic condition is perpetuated and facilitates the reparative processes, mental and physical. Rest, analgesics and opiates are all required in some patients to achieve freedom from pain.
- 4 To date, all roads of clinical investigation have converged at the individual and his variable reactions to heredity, nutrition, occupational hazard, weather conditions, infectious irritants (exogenous and endogenous), environment, and psychogenic factors. In one individual, one such stimulus acts as the excitator precipitating him into the arthritic syndrome, in another, the same stimulus may produce schizophrenia, or, the combination of several stimuli may be required in another to develop arthritis. The point of importance is that the individual holds the key to the puzzle, and only study, and intimate knowledge of the individual will provide the answer. Genuine psychotherapy gives the physician the knowledge, and the patient the aid, which each seeks. Though such treatment requires time, and the results seem intangible and immeasurable, the time will be well spent if definite, lasting physical results follow the recognition and restoration to normal of disturbed mental and emotional reactions.

"One of the essential qualities of the clinician is interest in humanity, for the secret of the care of the patient is in caring for the patient."¹⁰

effect in the production of arteriosclerotic changes in certain individuals. Liquid intake should not exceed six to eight glasses a day, and this amount should include fruit juices, water, soups and milk. This restriction of fluid is suggested especially in the overweight patient. Excessive liquid does not produce firm muscle, solid sound tissue, but produces an unstable labile matrix.

DEFORMITIES PREVENTION, CORRECTION AND OPERATIVE INTERFERENCE

To the orthopedic consultant falls a large and important part of the successful treatment of arthritis. On him devolves the task of preventing joint deformity if possible, correcting it when it has occurred, or if it occurs in spite of attempted prevention. The medical man's treatment of deformity consists of a few very simple things, simple because they are so obvious so far as indication is concerned, but far from simple when it comes to application and the production of results. They are usually preliminary to the

important as the operation itself, and this decision must be made by the physician who has had charge of the case, he who has knowledge of the entire picture with all its interrelated intricacies and disturbances. In this connection, an interesting point was brought out in recent study made in connection with the Robert B. Brigham Hospital Survey of Chronic Disease.⁹ The life courses followed by ninety-five dead arthritics showed four distinct and different curves. Course A represented a patient who with the onset of arthritis dropped to a lower level of activity, remained there for a time, then climbed back toward his former level and stayed at this level through the greater part of his remaining life. Course B showed a life course made up of definite periods of remission and relapse, and as the years passed, the trend gradually downwards, with lengthening and more frequent periods of relapse and shorter and fewer periods of remission. Course C showed a tremendous drop in the life line, over a variable period of time, from the expected 100 per cent of

THE FOUR TYPICAL LIFE COURSES SUPERIMPOSED ON ONE ANOTHER.

orthopedist's arrival. The first is alleviation of pain, the second, reduction of congestion and swelling, the third, maintenance of the affected joint in the best postural position possible, so that if ankylosis must occur it will at least occur in the most practical and serviceable position for the patient.

Surgery is usually necessary to correct real deformity. This in competent hands has proved of inestimable value, not only in restoring function to the particular joint operated upon, but in rehabilitation of the patient. In some instances, he may be enabled to retake his place in a competitive world, in another he may return to an ambulatory existence after years of chair life, or, in a third, he may regain only the ability to feed himself, to do small personal things with arms which had before been helpless. All these things do more than restore that particular lost function, they restore the individual's self-respect, give him back a certain degree of independence and self-respect, and at least promote partial independence. These are attributes essential to everyone's morale.

The decision as to the suitable time for such operative interference is in my opinion as im-

portant as the operation itself, and this decision must be made by the physician who has had charge of the case, he who has knowledge of the entire picture with all its interrelated intricacies and disturbances. In this connection, an interesting point was brought out in recent study made in connection with the Robert B. Brigham Hospital Survey of Chronic Disease.⁹ The life courses followed by ninety-five dead arthritics showed four distinct and different curves. Course A represented a patient who with the onset of arthritis dropped to a lower level of activity, remained there for a time, then climbed back toward his former level and stayed at this level through the greater part of his remaining life. Course B showed a life course made up of definite periods of remission and relapse, and as the years passed, the trend gradually downwards, with lengthening and more frequent periods of relapse and shorter and fewer periods of remission. Course C showed a tremendous drop in the life line, over a variable period of time, from the expected 100 per cent of

activity to a 50 per cent or 25 per cent level, because of extensive joint destruction and crippling, and the remaining life spent at this low level, often for years. Course D showed a course which progressed steadily downward to death, without appreciable remission, regardless of treatment or any one particular factor. Studies of the histories of these patients with their different reactions indicated that an individual followed a certain Life Course irrespective of age, duration of arthritic symptoms or so-called type of arthritis. The Course D group particularly demonstrated this fact. In it were patients from almost every decade of life. Both the young and the old in this group showed at death surprisingly comparable pictures in regard to age of bone and tissue, both failed equally to respond to any treatment, both made (for an arthritic) a relatively rapid journey to the grave. Operation on one in this group appeared to be a mistake, in each instance it merely hastened the patient on his downward course. Another impression, not fact, gained from the study, was that operation on an individual following Course C, if undertaken at an opportune moment, might well raise him to a modified

Tea proved a variable feast, usually being served only when there were guests. They went to bed when they were tired anywhere from 9 P M to 1 A M. They visited the toilet with complete irregularity. This irregularity of the toilet hour is an interesting phenomenon. Most fastidious people change their clothes, bathe and care for their teeth and nails according to a quite regular schedule. Yet this very essential act of elimination is left entirely to the whim and caprice of rectal sensation. Persons who work nights or who work on alternate morning and afternoon shifts are especially prone to constipation.

Gradually I formed the impression that although there are probably many factors which help to maintain constipation the chief one is lack of habit. It is at least possible that the regular daily defecation of the normal person is an example of the conditioned reflex of Pawlow. So long as the toilet visit occurs in its regular, customary place in the daily sequence, success is assured. In the constipated person there is no regular sequence. He waits until he has an imperative urge to stool and visits the toilet at very variable hours. In fact if he is taking cathartics the normal progress of his entire intestinal activity is more or less continuously upset. First he takes a chemical or mechanical irritant which lacerates his intestinal mucosa sufficiently to produce one or several loose stools and before the tract can return to its normal condition it is usually purged again.

B PLAN OF TREATMENT

In seeking to help these persons complaining of constipation this plan was followed. By dint of careful history and physical examination, including rectal examination and often a barium enema and gastro intestinal series the possibility of organic cause for their distress was ruled out as carefully as possible. The many lesions of which constipation may be a symptom have been repeatedly listed in the literature and need not be discussed again now. Two conditions which are sometimes not sufficiently considered may be mentioned. Dr E P Hayden has called to my notice the importance of rectocele as a cause of rectal constipation in women the rectum being mechanically unable to empty itself. Dr Langdon Parsons⁴, in a paper recently published has pointed out the surprising frequency with which some disturbance of bowel function is the first symptom of carcinoma of the stomach. When convinced that his symptoms were of functional origin I have then sat down with the patient and explained to him something of the physiology of the intestinal tract and the origin of most of his symptoms in irritation of the intestinal mucosa⁵. I have tried to dispel

his fear of constipation and to engage his enthusiasm and cooperation so far as possible. This step is time-consuming but I believe that it is absolutely essential. The patient will not embark on the program to be described if he does not understand and sympathize with the theory and plan of the physician. The patient has then been given written instructions as follows:

- (1) Have regular hours for sleep and particularly for rising in the morning.
- (2) Eat three meals at regular times every day with no nibbling between meals. (The menu is not stressed except to discourage the use of any excess of roughage for its laxative action.)
- (3) Drink at least eight glasses of fluids daily. (It is reasonable to suppose that if the body is not well supplied with water, relatively more fluid will be absorbed from the intestinal contents and leave them abnormally dry.)
- (4) Take at least thirty minutes of work or play daily preferably out-of-doors and sufficiently energetic to produce a little breathlessness and start palpable perspiration.
- (5) Visit the toilet for stool every day after breakfast whether any urge is felt or not. Stay there (without straining) fifteen minutes unless a thoroughly satisfactory result is achieved in less time and, when this period is over do not return until the next day at the same time if it can be avoided.

In only two instances was the above treatment modified in any way. One young woman, examined by barium enema, in spite of the usual preparation showed retention of impacted fecal balls. These were removed by repeated gentle enemata before beginning the program of habit training. I doubt if this precaution was strictly necessary but it probably spared her a few days of difficult stools before her regular habit was established. One elderly lady had considerable mucosal irritation as evidenced by excess of mucus in her stools and areas of muscular spasm of the colon which were demonstrated by the barium enema. Her progress toward a normal bowel habit was accelerated somewhat by the use of belladonna. She was given ten drops of the tincture before meals three times daily for about two weeks.

C RESULTS

Thus far there have been thirty-seven private patients who cooperated well and whom I have been able to follow satisfactorily. All are now symptom-free, most of them after only a few days to two weeks of treatment. Of patients seen in the Outpatient Department of the Massachusetts General Hospital only twenty-nine cooperated well and returned for follow-up examinations. Of these, twenty-five are now symp-

THE TREATMENT OF CONSTIPATION

BY ALLEN G BRAILEY, M D *

IT is quite probable that a greater total of impaired health is due to functional than to organic disease. Yet the treatment of functional conditions has lagged far behind that of the organic. Among the reasons for this lack of progress is the fact that it is often hard to discover the precise defect in the patient's personality, habits, or environment which cause his symptoms and, furthermore, that successful treatment requires his understanding and active cooperation, whereas the treatment of organic disease often requires only his passive assent. Thus, the correct diagnosis and treatment of acute appendicitis is not much more difficult in a person of low mentality than in the highly intelligent. The successful treatment of functional troubles is often a greater challenge to the ability, patience and ingenuity of the physician than is the dispensing of the proper remedy for better understood diseases.

Repeatedly in the history of medicine, groups of conditions have been poorly treated until one or more definite syndromes has been clearly separated from the mass and its cause discovered. For example, the group of conditions now recognized as due to hyperparathyroidism remained obscure until recent years, but now this disease is as easily diagnosed and treated as is exophthalmic goitre. In a similar way with further careful study, many functional disorders may be expected to fall into categories with relatively simple causes and yield to fairly standard treatment. The functional disorder of the gastro-intestinal tract, variously called constipation, unstable colon, unhappy colon, etc., is one such condition which I believe, is now ready for clearer understanding and more rational treatment.

A CAUSES OF CONSTIPATION

Four years ago, while working in the outpatient medical clinics of the Massachusetts General Hospital, I became impressed, first, by the large number of patients who said they were constipated, secondly, by the fact that they had usually treated their symptoms themselves or with the help of the drug clerk, and, thirdly, that we doctors, ourselves, often showed rather little interest in the complaint and had developed no generally recognized best method of treatment. The importance of constipation has been variously estimated in the past, from the view that it never leads to organic disease, to the teaching of Sir Arbuthnot Lane and his school that constipation is an important predisposing cause of such diseases as tuberculosis and cancer.

Even if one believes that constipation never causes permanent injury to the body, one must still admit that it does cause its victims a great deal of mental and physical distress, often daily and for a period of years and, therefore, it ought to have the interest of the profession.

Each person complaining of constipation was questioned as to what he meant by the term, as to the onset, duration and treatment of his complaints, and, finally, as to his daily habits of work, rest, diet, exercise and toilet. It appeared that nearly everyone meant, when he said he was constipated, that, if he stopped taking cathartics, his bowels did not move during the next twenty-four hours. He was always astonished when told, as pointed out by Alvarez¹, by Burnett² and others, that food takes from two to seven days to make the voyage of the intestinal canal in normal persons. With many of these patients, months had passed since they had given themselves an opportunity to demonstrate whether they were truly constipated. They also complained of fatigue, lack of ambition, mental depression, occasional vertigo, foul breath, eructations and abdominal distress and distention.

The time and conditions at the onset of these complaints had often been forgotten. Thaysen³, in a study of 375 constipated persons, found that the symptoms were well established before the twenty-sixth year in about three-quarters of them. When the onset could be definitely recalled, it was striking how often it appeared that their trouble began when they moved from one town to another, changed the nature of their work or were confined to bed for a time with some illness. Often they had taken laxatives daily since these upsetting events occurred.

A study of the daily habits of these patients gave interesting results. Persons who felt that their bowel action was normal and satisfactory were almost invariably found to live quite routine and scheduled lives. For instance, most business men with normal habits quite habitually rose at 7 A.M., shaved, ate breakfast, ran for the train and went to the toilet on reaching the office. Usually it would prove that lunch came regularly at 12 30 P.M., dinner at 6 P.M. and bedtime fairly regularly at 11 P.M. They often added "I sometimes have no stool on Sundays and I am apt to be constipated during vacations."

Persons with constipation, on the other hand, almost invariably gave a story of irregular days. If they had entertained late in the evening, they slept later next morning or had breakfast in bed. Luncheon at home was served at 12 30 P.M. but luncheons out were served at 1 30 or 2 P.M.

R B O

IN these days it is a common statement that 95 per cent of the early cases of leprosy are curable The writer has been treating leprosy for about twenty years but it was with poor success until the ethyl-ester of chaulmoogra oil became available With the preparations now procurable it is possible to do very much better than just the 95 per cent mentioned above

For convenience we may divide leper patients into four classes

(1) Early cases by which we understand those in whom the disease has gained only sufficient hold to make a certain diagnosis possible

(2) Moderately advanced cases, such as patients who can be recognized as lepers at a glance They are able to work as usual, but may have one or more ulcers They may have the so-called leonine expression, and have lost much of their eyebrows, but their activities are not yet limited by their disease

(3) Advanced cases These have huge stinking ulcers, but have no edema and can still work.

(4) Patients in the last stages In these the heart is beginning to fail, and their resistance is broken, so that they do not react to any treatment

Taking this classification, our experience during the past two years has been that 95 per cent of the moderately advanced cases and at least 75 per cent of the advanced cases are curable Those patients who are not curable are lost because of some other intercurrent disease, as malaria, pneumonia, etc

In our experience successful treatment depends on a careful study of each individual case There is no routine treatment which is the best for all Some do much better on one preparation and others on another Great care is also needed to find the optimum dosage for each patient For instance, we had one advanced case which a casual examination would place in the last stages We began with alepol, an ethyl-ester of chaulmoogra oil, put out by Burroughs, Wellcome & Co, and gradually increased the intravenous doses to 13 cc of a 3 per cent solution, once a week, which is more than twice the maximum dose recommended by the manufacturers This I further supplemented by giving him per oram another 6 cc of the same, some to be taken after each meal and mixed with enough water to last him a week He also had regular dressings for his ulcers as long as needed Ulcers 12 cm. long healed up in a little over a year The majority of patients however, cannot be given more than 10 cc once a

week, and some not more than 5 cc If the reactions are too severe they do not seem to profit by the treatment, and the dosage must be reduced before they gain Some improve faster on 6 cc than others on larger doses If they cannot bear doses large enough to make a reasonable gain, we shift to another preparation of chaulmoogra oil, or supplement the treatment by another drug The iodized ethyl-ester is extremely useful in skin lesions At a sitting ten or fifteen or even more intradermal injections, each of 0.1 cc, may be given These are very effective so that almost any skin lesion will clear up after a month or two, but without other treatment a relapse is certain to occur If larger doses of the iodized solution are given, nervous symptoms soon appear, and further treatment with it must be discontinued, or reduced and supplemented by another preparation

On this patient's hands where there is now healthy white skin, there was a mass of stinking ulcers

Everyone who treats leprosy has his own favorite drug and method We have found the alepol, given intravenously, the least painful and generally the most effective of our whole armamentarium It has the great disadvantage of obliterating the veins After a few months of treatment it becomes almost impossible to find a vein anywhere in the whole body, in which case it becomes necessary to substitute intramuscular injections, giving a series of 1 cc or less in various parts of the body, preferably near an ulcer if there is such If a patient happens to have varicose veins you are in luck so long as they last, which unfortunately is not long

It is generally stated that leper patients react badly to mercury and arsenic The contrary is true in our cases Indeed it is a frequent experience when a patient is not gaining as he should, to find that a few doses of one or the other will cause him to again begin to gain This has happened so often that we are giving more and more mercury to almost all of our leper patients It is true that many lepers are syphilitic and need mercury and arsenic for that reason, but those who are not are indubitably helped by it The

tom-free and consider themselves well. Of the remaining four, one only came to the clinic twice and there is perhaps some question whether she did faithfully carry out instructions. The other three were very nervous and emotional women with backgrounds of financial and domestic unhappiness. Even though not cured, they take only very small doses of mineral oil and feel much improved, which suggests once more that the symptoms associated with constipation are due, more often, to the irritation of repeated catharsis than to the irritation of retained intestinal contents. The nervous and emotional background of the patient⁶ is important, of course. But how often is the tendency of nervous people to constipation due to the fact that it is especially these people whose lives and habits are chronically irregular and poorly ordered?

This series of patients is too short to deserve detailed analysis. Persons of all ages are represented from the second to the eighth decades inclusive. The two oldest patients, one man and one woman, were both over seventy years of age and had both taken some cathartic regularly every night for over forty years. They were both rid entirely of their symptoms, their constipation and their pills at the end of one week. Suffice it to say that I have found no evidence, thus far, that age, duration of symptoms or previous therapy has any important effect on the results of treatment by this method. The one essential factor seems to be the willingness and the ability of the patient to cooperate faithfully in the development of a regular and normal stool habit.

I was greatly encouraged on reviewing the literature to find that this view of constipation and method of treatment are not at all new and that there are several published accounts of their successful application. So far as I can find, they were first formulated by Dr Paul Dubois of Paris in 1886 and discussed in more detail in his "Psychic Treatment of Nervous Dis-

orders" published in 1906.⁷ Dubois stated definitely that the great majority of constipated persons could be cured by this method. Lyon⁸ in 1908 acknowledged his debt to Dubois and adopted his method of treatment. Of 69 patients treated, all but one were completely cured without medicines of any kind. Marshall⁹, in a very interesting paper, referred to the work of Dubois and Lyon. His treatment is essentially that outlined above.

In spite of these satisfactory reports and of a fairly general recognition of the importance of regular habits, constipation is all too often poorly treated. It is hoped that many physicians may be encouraged to make a careful and thorough trial of this method of treatment and establish its importance by publishing their results.

SUMMARY

- 1 It is suggested that so-called constipation, not due to organic disease, is the result of lack of a regular toilet habit.
- 2 An outline of treatment based on this concept is given.
- 3 All of thirty-seven private patients and twenty-five of twenty-nine outpatients, treated in this way, were entirely relieved of their symptoms without the use of medicines, lubricants or enemata.

NOTES ON THE TREATMENT OF LEPROSY

BY CYRIL E. BOUSFIELD, M.D.*

FOREWORD

WHATEVER difference of opinion may exist concerning the religious value of foreign missions, there can be no doubt as to the social value of the medical missionary. In remote regions where abject poverty is the lot of the masses, religion and medicine may well walk in the closest company, and serve in the most complementary manner. It has been a great privilege to know and to feel the spirit and skill of the writer of this article on the treatment of leprosy.

Dr Cyril E. Bousfield has given the best part of his life to medical service in China. He leaves his isolated and harried hospital very occasionally, and then only to learn new methods of medicine and surgery. He must practice them often in great danger. The section has been infested with bandits, and misunderstandings of the new western ways seem endless. His religion makes him unafraid, and his knowledge gives him confidence. There is no reward of acclaim or wealth. It is a service of as fine unselfishness as the world knows, demanding courage and resourcefulness, wisdom and patience. Dr Bousfield's brain contemplates and weighs, his hands do brave and delicate things,

*Bousfield, Cyril E.—Medical Director, American Baptist Mission Hospital. For record and address of author see *This Week's Issue* page 1131.

personal service will almost surely make a poor family doctor. Many of our leading specialists were formerly good general practitioners and then concentrated their efforts to the one branch of medicine in which they could excel and serve humanity best.

Some may think it hard to be called at night to attend the sick, but the joy the family doctor often feels when he has made such a call possibly saving a human life or relieving suffering, is well worth all the hardship, even if the small fee earned is never paid.

Early in my professional career I decided that I would rather be known as a good successful general practitioner than as a poor governor of the state. I cannot imagine any profession more self-satisfying than that of a family physician who cares for his regular families one decade after another, assisting the babies into the world, and easing the pains of the aged dying. The family doctor soon gains the love and respect of the entire family sharing with them life's joys and sorrows. Each member of the circle confides in him and seeks his advice well knowing that the one who helps to keep his body healthy and his nerves steady can be depended upon for unlimited sympathy and complete understanding.

Then, too, the practice of medicine in country districts is, I believe, more interesting in many respects than in large centers of population as the more we must rely upon our own resources the greater the challenge to our capabilities. Extremely difficult cases act upon our interest as spice in our food. Dull indeed is the day when the family doctor treats only common cases.

It is a pleasant memory to recall being summoned in the night to a home reached only over roads that were impassable except to a horse, to find there a foreign-speaking woman who had been in labor for two days attended by a so-called midwife who fled when a little hand appeared. There was no one to assist and only one small dim lamp and one rusty pan for solutions, black dirt of many weeks' or months' accumulation on body and limbs, the uterus in constant contraction and the patient refused the use of drugs or anesthetics. (The mother and baby made an uneventful recovery.)

Then again a fractured femur or shattered tibia in homes too poor to afford even hospital expenses, taxes one's skill to get perfect results with few facilities at hand with which to work.

Nor need we be offended when asked by an elderly man, living alone and too poor to pay a

veterinarian, to save the life of his only companion a collie dog with ten little puppies, by applying a cast to a badly fractured hind leg. (Most satisfactory was the result. Complete recovery of the dog and a grateful man.)

One of the most challenging realizations to the general practitioner is the fact that he must attempt to know something of every disease which afflicts the human body and that consequently he can scarcely excel in any one thing. He must therefore look around and recognize those of his colleagues in every branch of medicine who know more in their particular practice than he. (Excepting always the soul to soul relationship of a family physician and his patient.) It is the duty and the privilege of the general practitioner to seek the advice and help of the specialist in every doubtful case possible. I consider it almost criminal for a physician to continue treating a serious illness alone if he knows another who could possibly aid him if called into consultation. In addition to the direct benefit to the particular patient every such consultation can be a source of knowledge to the physician calling on a specialist for help.

However the consultant is often at a disadvantage. He may have never seen the patient before while the family doctor may have studied his patient over a long period of time. The family physician needs sufficient courage to stand up for his convictions until proved wrong.

On the other hand, the family physician should not ask those financially unable to pay for a consultation with an expensive specialist, to undertake such obligations if he believes himself capable of treating the patient, even if such treatment should come under the heading of a specialty.

The one great need of the general practitioner is to keep in touch with some hospital, to attend every medical society meeting possible to grasp every opportunity to listen to special lectures, and to never cease to be a student.

Any system of state medicine, so-called, as adopted by some foreign countries and as advocated by some here, that disturbs the relationship between the family doctor and the patient discourages the very heart and soul of many who practice medicine as the devout practice religion (in the belief that the people who are best served are those who have a family physician and allow him to guide them along the ways to health) on all of which I base my claim that the most necessary branch of the medical profession is that of a general practitioner or the so-called family doctor.

arsenic preparations used are neoarsphenamine and sulphotreparsan, and the mercury used is Burroughs, Wellcome and Co's avanyl, a mercury preparation made especially for leprosy, and Parke, Davis & Co's mercurisal, or mercuric iodide or mercurous iodide per oram. It may here be noted that when we give the pure chaulmoogra oil, we give only the very best obtainable. Years ago many of my leper patients suffered intensely and I failed because I used any oil that happened to be on the market. For some of our patients hyrganol seems best. It is a French preparation put out by Poulenc Frères, Paris. I have tried quite a few others, as sodium gynocardate, and sodium morrhuate, put out by Smith Stannistreet, Co., Calcutta, but with poor results. Recently solganol, a Ger-

This shows how the process of destruction stops and even though the ends of the fingers may be lost they heal up entirely

man gold preparation, has been very highly recommended. We have tried it out on two cases only, for it is very costly. In both, the euphoria it induced was really remarkable. The two patients were very enthusiastic about it but I could not see any improvement which would justify its continuance. Probably the ideal method would be to use it in addition to the regular drugs.

It is unnecessary to mention here the importance of ridding these patients of helminthic infestation, malaria, syphilis, etc., when present.

In China, at least, leper patients differ from

all others in many respects. They all not only have an inferiority complex, but in addition they fear the rest of their race. They are shunned and avoided till they are ready to prefer death to life. Then, as they become hardened to the attitude of others, utter indifference to all decency and respectability is liable to supervene. When an early case comes he will often throw himself at your feet, and with tears streaming down his face, implore you to save his life. When the disease has advanced, they come in a dull despair and ask you to help them, in a way that makes you think they have no hope of your being able to do so. The practice of the present Government in China, in many places of shooting all lepers, helps to aggravate their mental attitude. However as they see themselves really being healed, this is quickly changed. They get new clothes and clean themselves up till sometimes you hardly recognize your own patients.

When treatment is undertaken, success depends, at least in our experience, on a careful study of each individual case, and in making the patient feel that he is responsible for his own cure, and you are just going to help him to recover. He is warned that it will be a long, hard fight, but that he will surely win if he is willing to pay the price. They are more cooperative than most patients and more grateful for what you do for them, than any other class of patients I have met anywhere in the world. I always make it a practice to ask them carefully about the reaction to the last treatment, and about the pain, if any, caused by it. I tell them what medicine I propose to give them, and to keep in their minds the idea that they are responsible for their own cure, I ask them if they want it or something else. By this way you get them to take better care of their ulcers, diet, etc. The work is often extremely unpleasant, and the stench of the ulcers, in some of the new cases, is too horrible to describe to those who do not know of it, but it is our job, for the Master said, "Cleanse the lepers," and there is real joy in seeing a disease conquered which for ages has been esteemed incurable.

THE FAMILY DOCTOR*

BY ORAN A. MOSER, M.D.†

THE practice of medicine is one of the greatest of the professions, and the family physician is and always will remain the most necessary part of the medical profession.

As the young graduate ponders over the problem of which branch of the profession he should enter, he gives thought to the long and uncertain

*Address delivered by the retiring President of the Hartford (Conn.) County Medical Association at the one hundred and forty second annual meeting.

†Mosen Oran A.—President Hartford County Medical Association 1933-1934. For record and address of author see "This Week's Issue" page 1131.

hours and small fees of the general practitioner and does not find the prospect attractive. In comparison, the shorter office hours and regular routine, with larger fees, of the specialist appear more alluring. Consequently there has developed a situation in which there are too many specialists as compared with general practitioners. And yet I would not advise any young graduate to attempt to become a family physician unless he can love that branch of the profession. He who puts financial gain ahead of

believe that the psychiatrist tends to favor the prisoner, Guttmacher insists that some cases have received more severe sentences because of his report to the court. He upholds the principle of treating the criminal rather than the crime and advises indeterminate sentences. He quotes Justice Cardozo who in 1928 stated "Everyone concedes that the present definition of insanity has little relation to the truth of mental life." He pays tribute to the Briggs Law of Massachusetts which has had such a beneficial effect in doing away to a very large extent with the battle of experts. Guttmacher details the results of his examinations and gives further recommendations for dealing with medico-legal problems.

There has been further interest stirred up in the whole problem of prevention of mental and nervous disease and defect by various eugenic programs, including sterilization and birth control. It is obvious that until there is a more general agreement as to the hereditary nature of many of these conditions it will be impossible to formulate a satisfactory program for prevention. An article by A. Lewis in the *Eugenics Review* 25:79, 1933, entitled "Inheritance of Mental Disorders" claims that the manic-depressive psychoses are highly transmittable, that if one parent has the disorder one-third of the children will inherit it, whereas if both parents have the disorder two-thirds of the children will be affected, and the remaining third will be somewhat unstable emotionally. Schizophrenia is considered to be less due to hereditary factors. However, the author claims that if one parent has the disorder approximately ten per cent of the children will inherit it and forty per cent will show a schizoid type of personality, so that only half the children will be normal mentally. If both parents have schizophrenia half the children will inherit the disease and only one-fifth will be normal. Lewis does not believe that compulsory sterilization is a solution to the problem of mental disease, claiming that many apparently healthy persons will transmit the tendency, so that it is not possible to select properly those who might transmit mental disease.

The German literature, in particular, has a number of articles on this problem. With the compulsory sterilization program adopted by the German government it is obvious that there should be such discussion. Most of these articles advocate sterilization and some even recommend castration, one author advising castration of all violently insane persons with the idea that it will have a calming effect upon them. Apparently the courts in Germany have had a very conservative attitude on the subject of sterilization, and a physician performing vasectomy even with the patient's consent might be threatened with from two to ten years in the penitentiary.

There is considerable reference to the laws concerning sterilization in the United States and particularly to the practice as carried out in the State of California. On the whole it would seem that the idea of eugenic sterilization particularly for the prevention of mental disease and mental defect is being more generally approved.

There have been a number of articles relating psychiatry to the work of the general practitioner. As an example might be cited Gordon Berry's article, "The Psychiatry of Progressive Deafness" in the *Journal of the American Medical Association* for November 18, 1933, in which he points out the various difficulties of the deaf person. In the young child there is often a tendency to withdraw, to become self-centered and sensitive, and to be misjudged by parents, teachers and comrades. Many persons refuse to face the fact that they are deaf, which leads to further difficulties. An attitude of suspiciousness is easily developed under such conditions and the child tends to blame others. The author details some of the best ways of dealing with these situations. He mentions the value of certain new devices for increasing hearing, the importance of learning lip-reading and the necessity of continuing social contacts. With regard to vocational adjustment he feels that there are some types of work in which deafness is an asset rather than a liability.

The problem of alcohol and drug addiction has received considerable attention. Little new material has appeared on this subject. In general there is the continued tendency to emphasize the importance of personality study in those who use alcohol and drugs and to feel that some sort of psychological analysis is necessary in the cure of these cases. The psychoanalytic group continues to emphasize the homosexual factor as one important cause of alcoholism. In general, the attitude is that alcoholism and drug addiction are symptoms of a maladjusted personality. There is further literature on the use of insulin in the treatment of morphine addiction. Apparently this method of treatment is advocated by some writers, whereas others see little of value in it.

There have been some rather interesting articles on suicide. The article by Frederick C. Lendrom in the *American Journal of Psychiatry* 8:479, 1928-1929 entitled "One Thousand Cases of Attempted Suicide Admitted to the City of Detroit Receiving Hospital" points out that seventy-two of these cases resulted in death. Apparently suicide is attempted more often by females but with greater success by males. The greatest incidence is between the ages of twenty and thirty. Suicide is attempted much more frequently by Protestants than by Catholics. Unemployment is apparently a factor. Suicide is

MEDICAL PROGRESS

PROGRESS IN PSYCHIATRY FOR 1933

BY KARL M BOWMAN, M D *

ONE of the most important events in the field of psychiatry during the past year was the Annual Meeting of the American Psychiatric Association which was held in Boston from May 29th to June 2nd. Dr James V May, Commissioner of the Department of Mental Diseases, was president of the Association and presided at the meeting.

A new constitution was adopted by the Association which indicated some slight changes in attitude. Formerly membership had been encouraged and any physician interested in psychiatry was welcomed to membership. The new constitution allows for associate members who "shall be physicians who have had at least one year's practice in a mental hospital", members "who have specialized in the practice of psychiatry for at least three years", and fellows "who have specialized in the practice of psychiatry for at least six years".

It was felt that the Association should establish certain standards and certify individuals as qualified psychiatrists. An examining board of five fellows was appointed to pass on all applications for membership, and in addition the Association contemplates the issuing of a certificate or diploma which will be kept sufficiently difficult to obtain, to cause its possession to be regarded as of considerable value. The plans for the issuing of such certificate or diploma have not been fully worked out as yet. Back of this decision by the Association is the feeling that many persons have posed as psychiatrists who have had very inadequate training, and it was felt that either the American Psychiatric Association must come forth with definite standards or other medical organizations would take upon themselves such a function. It is quite possible that this issuing of the diploma or certificate will be carried out in cooperation with other organizations, as for example, the American Medical Association.

Of equal interest was the Conference on Psychiatric Education which was held for two days preceding the meeting of the American Psychiatric Association under the auspices of the National Committee for Mental Hygiene. This conference was presided over by Dr C Macfie Campbell, Professor of Psychiatry at the Harvard Medical School, and some twenty-eight psychiatrists, most of them professors of psychiatry in medical schools, attended. This conference discussed the undergraduate and grad-

uate teaching of psychiatry. It was the feeling of this group that definite standards for higher qualifications in psychiatry should be worked out, and the idea of awarding a diploma in psychiatry was endorsed. It was felt that candidates for such a diploma should have had at least one year's internship in an accredited general hospital, three years' study in or under the auspices of an accredited mental hospital, and three years' additional experience as a minimum requirement for examination for a diploma.

The teaching of psychiatry in the undergraduate courses in medical schools was discussed and various members gave their views as to the best method of teaching psychiatry. It was agreed that the psychological and psychiatric viewpoint of human behavior at all age levels should be introduced in the pre clinical years in the medical school curriculum, and that clinical psychiatry should be further developed in many of our medical schools.

Of interest along the same line is a pamphlet of some fifty-eight pages entitled "Psychiatry in Medical Education" by Ralph A Noble, M.D. published by the National Committee for Mental Hygiene. This pamphlet summarizes the findings of Dr Noble after spending two years studying the teaching of psychiatry in this country. There is a careful description given of the method of teaching employed at nine of the leading medical schools of the country.

A further article dealing with this same topic is entitled "Preparation for Psychiatry" by Adolf Meyer in the *Archives of Neurology and Psychiatry* 30 1111, 1933. Meyer insists that the domain of psychiatry is the study and treatment of all abnormal conditions involving man's behavior. He gives in considerable detail the method of instruction which he regards as most desirable and details some of his own formulations of psychiatric conceptions.

In the field of forensic psychiatry we find constant emphasis on the difficulties of reconciling the medical and legal points of view with some suggestions as to improving general conditions. One article of particular interest is entitled "Psychiatry and the Courts" by Manfred S Guttmacher appearing in the *American Journal of Orthopsychiatry* for April, 1933. Dr Guttmacher, after two years' experience as psychiatrist for the Supreme Court of Maryland, discusses many of the difficulties. He feels that psychiatry deals with personalities while the law deals with generalizations. Although many

*Bowman, Karl M.—Chief Medical Officer, Boston Psychopathic Hospital. For record and address of author see "This Week's Issue" page 1131.

believe that the psychiatrist tends to favor the prisoner, Guttmacher insists that some cases have received more severe sentences because of his report to the court. He upholds the principle of treating the criminal rather than the crime and advises indeterminate sentences. He quotes Justice Cardozo who in 1928 stated "Everyone concedes that the present definition of insanity has little relation to the truth of mental life." He pays tribute to the Briggs Law of Massachusetts which has had such a beneficial effect in doing away to a very large extent with the battle of experts. Guttmacher details the results of his examinations and gives further recommendations for dealing with medico-legal problems.

There has been further interest stirred up in the whole problem of prevention of mental and nervous disease and defect by various eugenic programs, including sterilization and birth control. It is obvious that until there is a more general agreement as to the hereditary nature of many of these conditions it will be impossible to formulate a satisfactory program for prevention. In general, the attitude is that alcoholism and drug addiction are symptoms of a maladjusted personality. There is further literature on the use of insulin in the treatment of morphine addiction. Apparently this method of treatment is advocated by some writers, whereas others see little of value in it.

There have been some rather interesting articles on suicide. The article by Frederick C. Lendrom in the *American Journal of Psychiatry*, 8:479, 1928-1929 entitled "One Thousand Cases of Attempted Suicide Admitted to the City of Detroit Receiving Hospital" points out that seventy-two of these cases resulted in death. Apparently suicide is attempted more often by females but with greater success by males. The greatest incidence is between the ages of twenty and thirty. Suicide is attempted much more frequently by Protestants than by Catholics. Unemployment is apparently a factor. Suicide is

most commonly attempted in the evening and at the week-end, especially Sunday or Monday. Poisoning was the most common means attempted, and tincture of iodine was the drug most commonly used.

Of considerable interest is an article by Leo Kanner in the *American Journal of Psychiatry*, 8: 171, 1933, entitled "The Significance of the Complaint Factor in Child Psychiatry." Kanner points out that to write down the abbreviated complaint in the record often is to miss the essence of the case. The apparently irrelevant remarks by the parent in connection with the problem often give the clue to the whole situation. This article merits reading by all physicians, but particularly by the pediatricians.

No important new theories concerning mental disease have come out during the past year. Bancroft's theory of colloidal dispersion and the use of sodium rhodanate and sodium amylal has attracted very little attention, and the articles published all indicate that this theory seems inadequate to explain the mental disorders. In the treatment of mental diseases we find that there is continued interest in the use of carbon dioxide and sodium amylal. It seems to be generally agreed that temporary improvement may follow the use of these two methods but that no permanent cure will be achieved. The articles discussing the removal of foci of infection and the use of endocrines are largely repetitions of material which has already been published. Further studies into the nature of the schizophrenic process indicate that there may be certain physiological variations occurring with this disease but so far nothing has been discovered which gives any clue as to the etiology.

The treatment of neurosyphilis by fever therapy and arsenic is now considered a reasonably

satisfactory method. It appears that the best results are obtained by the use of malaria and tryparsamide. Rat-bite fever and diathermy are less satisfactory than malaria, although they may be preferred for certain selected cases. There has also been considerable use of quite simple methods of causing fever such as hot baths, injection of foreign proteins and the electric blanket. By the use of malaria and tryparsamide a fair percentage of cures is being obtained by various groups so that it seems fair to expect that approximately one-third of the cases treated by this method will recover to a sufficient degree that they can go out into the community and become self-supporting. When one realizes the pessimistic attitude of twenty years ago or even later, it will be seen what marked advance has taken place in the treatment of this disorder.

The psychoanalytic group have continued to publish a great deal of material, but there have been no really new variations in the psychoanalytic theories. Of considerable interest is an article by Leo Kessel and Harold T. Hyman in the *Journal of the American Medical Association*, November 18, 1933, entitled "The Value of Psychoanalysis as a Therapeutic Procedure." In this article thirty-three cases treated by psychoanalysis are studied. In approximately half of these cases no benefit was obtained, and the authors conclude that persons suffering from a definite psychosis or persons over forty years of age are not likely to benefit by this method of treatment. Slightly more than half of the total number of cases treated were benefited. In five cases, or fifteen per cent, it was felt that the patient was definitely cured by psychoanalysis. In the remaining fifteen cases it was felt difficult to decide how much the improvement was due to psychoanalysis and how much to other factors.

A TRUST FUND FOR THE HEBREW UNIVERSITY

A trust fund of approximately \$200,000 (£39,000) has been created by anonymous donors to be used over a period of ten years for the establishment and maintenance of a department at the Hebrew University for research into the causes and cure of cancer, according to an announcement made by Dr. Judah L. Magnes, Chancellor of the Hebrew University in Jerusalem at the conclusion Sunday May 13, of a series of conferences with the American members of the Board of Governors of the University. Dr. Magnes announced that it is the intention of the University to use part of the available funds for the erection and adequate equipment of special laboratories at the University.

The plan worked out by the Hebrew University provides for research in radio-biology, physiological chemistry and the study of cells and tissues.

The University proposes to begin its work in cancer research in those fields in which the material at hand is sufficient to place the laboratories on a level with similar scientific institutions in Europe and America," said Dr. Magnes.

The study of the cell and that of physiological chemistry have become indispensable for the investigation of the nature of carcinoma and its manifestations in the diseased organism according to a statement by Professor Ludwig Halberstaedter, internationally recognized as an expert in the treatment of malignant tumors, who is now in charge of the station for cancer therapy at the Rothschild Hadassah Hospital in Jerusalem. He brought with him to Palestine a supply of radium amounting to about two hundred milligrams. Dr. Georg Goldhaber of Berlin has already been appointed to assist Professor Halberstaedter in his researches. Dr. Goldhaber is attached to the University's Institute of Physics.

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL PATHOLOGIC EXERCISES

EDITED BY RICHARD C. CABOT, M.D.
F. M. PAINTER, A.B., ASSISTANT EDITOR

CASE 20211

The following case is the third in the group of which the first two cases were published last week.

PRESENTATION OF CASE

A fifty-three year old Canadian pattern maker entered complaining of abdominal pain and constipation of three weeks' duration.

Three weeks before admission he began to notice indigestion. This was characterized by a sensation of heaviness and discomfort in the epigastrium. Associated with this was mild constipation. After he had taken some pills given by a physician the attack cleared up. There had been no nausea, vomiting or severe abdominal pain with this attack. One week later he experienced severe abdominal cramps radiating across his abdomen from his umbilicus to the small of his back. The pain came on slowly, was persistent but varied in severity. He had several severe attacks every day until admission. During the two weeks before admission he ate very little. His bowels moved practically every day, although the movements were small. Two days before admission he took an enema which was followed for the next two days by more severe cramps than he had had before. The day before admission he vomited. He had no distention, jaundice or tarry stools. There had been no exposure to lead.

His general health had been very good. He had an appendectomy sixteen years before admission. The following year he had pneumonia.

His family and marital histories are non-contributory.

Physical examination showed an undernourished man lying quietly in bed in no discomfort. Both supra- and infraclavicular fossae were very prominent. Examination of the chest showed a circumscribed area of impaired resonance on the right posteriorly from the fifth to the ninth vertebral spaces. There was slightly diminished vocal resonance in this same area. There were no râles. The abdomen was moderately distended, voluntarily spastic but not tender. Peristalsis was hyperactive. There were no masses. Rectal examination was negative.

Examination of the urine was negative. The blood showed a red cell count of 5,500,000, 80

per cent hemoglobin, and a white cell count of 11,300 with 89 per cent polymorphonuclears. The stools were of liquid consistency, contained much mucus and starch, and were guaiac-negative. The non-protein nitrogen was 27 milligrams. The chlorides were 599 milligrams.

X-ray examination showed that the diaphragm, the costophrenic angles and the lung fields were clear. A gastro-intestinal series showed some spasm in the prepyloric area. The duodenal cap showed a slight irregularity which was not definite enough to warrant a positive diagnosis of ulcer, but was quite suggestive. The six-hour examination showed no gastric residue. A barium enema was negative.

Three days after admission operation was done. Following it the patient had mild abdominal pain. There was no vomiting or coughing. He died two days later.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES: The films taken of this patient's chest show a condition which we often see and about which we never feel quite certain. Notice the extremely small heart shadow. I do not know whether this is due to rotation of the heart so that we are looking at it in the transverse position or whether these patients actually have small hearts. It is a problem of some interest. The lung fields are very large and appear as though he had a moderate degree of emphysema.

In regard to the films of the stomach, I cannot add anything to what has already been said.

FURTHER HISTORY

The preoperative diagnosis was partial intestinal obstruction. An exploratory laparotomy was performed. A right paramedian incision was made between the old scar and the midline. There were no adhesions to the under surface of the previous scar, but a loop of ileum was angulated and stuck to the posterior wall of the abdomen to an extent which seemed sufficient to produce an obstruction. This was freed. The colon was palpated through its entire extent. Lumps of barium were present from the splenic flexure downward but none proximal to it. The stomach was palpated and visualized, and so far as could be determined was negative. The esophageal opening in the diaphragm was palpated but nothing abnormal was noted. There were adhesions from the gall bladder to the duodenum but the gall bladder felt soft and flexible and contained no stones so far as could be told. One small adhesion was cut. The appendix stump could be seen and was not adherent. The right inguinal ring was palpated, no evidence of a sac could be felt. The ileum was searched for a Meckel's diverticulum but none was found. The abdomen was sutured without drainage.

DIFFERENTIAL DIAGNOSIS

DR EDWARD L. YOUNG, JR. "Three strikes and out" Two strikes so far, and as I read this case history I can't quite see a home run. I expected not to know what was found at operation, but I do not see that having it I am much farther along.

The duration of symptoms, the fact of a previous operation with the possibility of adhesions and the type of symptoms which he is having all point toward a subacute intestinal obstruction. On the other hand, we are not told that pain is precipitated by the intake of food, which is apt to be true of the partial obstructions. Moreover, except on one occasion, he did not have nausea, which is generally present in partial obstruction. The other causes of abdominal pain were apparently considered and ruled out so far as possible. They mention in particular the study of lead colic and the study of the cardiac condition. There is no evidence of a small epigastric hernia which may be present, difficult to recognize, and which gives pains similar to these. The intermittent character of the symptoms suggests a chronic intussusception which, though rare, does occur, but here again there should be some evidence of it either in a positive guaiac or intermittent nausea or a palpable mass. I do not see any indication in the story to point toward any other lesion such as, for instance, duodenal or gastric ulcer, gastric cancer would seem to be ruled out by the short story, by a good hemoglobin and red cell count. So that it seems to me to come down to the question whether the patient has enough symptoms to justify operation. This was apparently so, and it seems to me that the preoperative diagnosis will have to be probable subacute intestinal obstruction, but a careful exploration must be done if, as I expect, a definite obstructive point is not found.

As regards his death, I see nothing here to tell us why. So far as they give us any evidence of any other system of organs, they are normal, the non-protein nitrogen is where it should be, and nothing else is given us that is out of line. I must confess that I cannot make an absolute diagnosis. I apparently have followed very much the same line of reasoning that went on in the minds of those in charge of the case. It seems to me that the only way to handle it was an exploration. The only justification for making a diagnosis of mesenteric thrombosis is the bad company that we are in, as the other two cases had it. From the description and the operation I cannot quite tell whether what they found would justify a very optimistic opinion as to the causative relation of what they found to the symptoms. It is too often true that "the wish is father of the thought." Logically and on the theory of chances, this patient had a cause of subacute intestinal obstruction which

was searched for but not found. He died as a result of one of the terminal accidents, an atypical embolus or peritonitis or possibly a mesenteric thrombosis.

CLINICAL DIAGNOSES

Subacute intestinal obstruction.
Generalized peritonitis.

ANATOMIO DIAGNOSES

Pylethrombosis with extension to the major divisions of the portal system, including the splenic division.
Gangrene of the small bowel.
Infarcts of the liver and total infarction of the spleen.
Generalized peritonitis.
Mural thrombus of the abdominal aorta, celiac axis orifice.
Operative wound, freeing of adhesions in the right iliac fossa.
Purulent pericarditis.
Arteriosclerosis, slight aortic and coronary.
Chronic pleuritis, bilateral.

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY This patient also died of mesenteric thrombosis. In contrast to the first two cases—you remember each of those had a very fulminating onset with a rapid appearance of prostration and shock—this man had over two weeks of symptoms of a relatively mild character. I believe one almost always thinks of mesenteric thrombosis in terms of fulminating disease and overlooks the possibility of the slowly developing case. In this case the portal vein and the splenic vein contained old grayish white thrombi which must have been present for a matter of two or three weeks at least. He had had them long enough so that he was beginning to develop a compensatory circulation between the spleen and the gastric plexus. There were large veins running from the hilus of the spleen to the greater curvature of the stomach, if he had survived a few weeks or months longer he would have had well developed esophageal varices, and might eventually have died from the rupture of one of them. The collateral circulation, however, had failed to develop rapidly enough to prevent total infarction of the spleen. The thrombi also extended well up into the portal branches in the liver, and there were multiple infarcts of the liver, which is a relatively uncommon lesion.

In all three of these cases I think it almost impossible to make a diagnosis from the history. The one person who could have made the diagnosis was the operating surgeon. It seems to me that a more careful exploration of the abdomen might have established the diagnosis in each of these cases. I do not know how great

the change in appearance was between the time of operation and the time of autopsy. Undoubtedly the frank gangrene we found postmortem was not present at the time of operation, but I think that the swollen cords of the veins could have been felt in two cases and the absent pulsation in the artery in the third case; if the patients were in good enough condition to permit of reasonably thorough examination, which may not have been the case.

DR YOUNG: Was there any fluid reported in any of these cases, particularly this last one?

DR MALLORY: It was present at the time of autopsy, but not at operation.

DR YOUNG: Because it should have been in the abdomen at the time of operation. Was it, Dr Boyden?

DR A. M. BOYDEN: No.

DR HOLMES: Was there any change in the heart?

DR MALLORY: The heart was a small one, Dr Holmes. It weighed 275 grams, which would be normal for a woman, but is definitely small for a man of fifty.

A SURGEON: You do not recall how much free fluid there was in the abdomen in this last case, do you?

DR MALLORY: About a liter and a half, hardly enough to pick up clinically.

DR HOLMES: During the acute attack would not the small bowel be paralyzed?

DR MALLORY: The actual area of involvement almost certainly would have been the segment above might well be spastic, however.

DR HOLMES: It seems to me if we had taken a plain film of the abdomen when the patient was acutely ill we might have shown the presence of gas and the absence of normal peristaltic formation in the small bowel and perhaps have made the diagnosis.

A PHYSICIAN: Do we know what the white cell counts were?

DR MALLORY: In general low, in the last case 11,000. In the first case it was 12,000 and in the other case about 17,000.

CASE 20212

PRESENTATION OF CASE

A thirty-four year old single white American was brought into the Emergency Ward in coma.

The day before entry his companion noted that the patient's speech suddenly became very thick and that he had a peculiar look on his face. He made him sit down and called for help. By this time the patient was unconscious and it was noted that his left side was stiff and motionless. He was taken home and put to bed. There he responded to questions and it was noted that the left side of his face was paralyzed.

He lapsed into a semistuporous state, in which he remained.

He had always been strong and healthy. Fourteen years before entry he passed a kidney stone. One month before entry he complained of dizziness and remarked that he probably needed glasses.

Physical examination showed a well nourished, plethoric young man in coma and incontinent. The pupils were small and reacted to light. The fundi were slightly choked and showed marked nicking of the veins. The heart was not enlarged. There were no murmurs. The blood pressure was 190/100. The left side was motionless. The reflexes were greater on the left than on the right, but were hyperactive on both sides. There was left patellar and ankle clonus and a bilateral Babinski.

The temperature was 102°, the pulse 120. The respirations were 28.

Examination of the urine was negative. No examination of the blood was done.

Lumbar puncture performed at half-past five p.m. on the day of admission showed an initial pressure of 400. The fluid was grossly bloody. After withdrawal of 50 cubic centimeters the pressure went down to 180. The fluid showed a negative Wassermann, total protein 34S, colloidal gold 3445555551, sugar 187, chlorides 743. Another lumbar puncture was performed at eight p.m. that same day. The fluid was also grossly bloody. The initial pressure was 250, falling to 150 after withdrawal of 10 cubic centimeters. Two more lumbar punctures, one performed at midnight and another the following day, both gave grossly bloody fluid under a pressure of 350.

DIFFERENTIAL DIAGNOSIS

DR. HENRY R. VIETS: The striking thing about this case is the fact that a young man of thirty-four, previously entirely well except for a kidney stone, suddenly became semistuporous and ultimately went into coma. At the same time there were signs indicating a hemiplegia on the left side. Naturally, in view of this onset, one thinks of an intracranial vascular accident. The suddenness of onset might lead one to think of embolus did we not know about the spinal fluid, which showed gross blood and thus was distinctly unfavorable to that diagnosis.

The patient may have had a brain tumor with a hemorrhage into it. He had, however, no signs of increased intracranial pressure and there was nothing in the previous history to suggest tumor of the brain. We know, moreover, that hemorrhage into brain tumors, giving what appears to be a sudden onset, is not nearly so common as it was previously considered to be.

The history, therefore, of this young man speaks very strongly for a vascular lesion. It might be due to a cerebral artery disease.

eurysm, arteriosclerosis, or vascular lues. The possibilities of all three must be considered.

We did not know until the examination took place whether the man had lues or not. The negative findings in the spinal fluid and the negative blood Hinton were strong evidence against it and I do not believe we can consider his condition on that basis.

The examination gives some evidence of arteriosclerosis, especially the examination of the fundi. There was definite nicking of the veins when the arteries passed over them, a condition not usually seen in a man as young as this. The patient also had a hypertension, at one time the blood pressure was 190/100 and at another the systolic pressure was 180. In spite of these two findings it does not seem to me likely that we are dealing with a case of ordinary rupture of an arteriosclerotic vessel. This opinion is largely based upon the age of the patient, although such a diagnosis could not be ruled out entirely from the history alone.

Rupture of an aneurysm is a much more common finding, and the history of the sudden onset in this man seems to be entirely consistent with this diagnosis. The gross blood in the spinal fluid on repeated examination and the fact that he survived only a short time are also consistent with the diagnosis. The hemiplegia might easily be due to an aneurysm if the defect in the vessel happened to lie in a place that would allow blood to spread over the cortex of the brain on the right side. There is a possibility, however, that a lesion deeper in the brain, which would also give hemiplegia, will be the underlying pathologic finding. We do not have a history of progressive hemiplegia and therefore the site of the lesion is or near the internal capsule, giving a complete hemiplegia suddenly, is most likely. On the other hand we have to account for the gross blood in the cerebrospinal fluid, which can only be found when the lesion is in or near the subarachnoid space. I should think, therefore, from the history and from the examination one would strongly suspect a ruptured aneurysm on the right side of the brain, giving the sign of left hemiplegia, or possibly a subcortical hemorrhage, perhaps due to aneurysm giving much the same picture. This syndrome, if I am correct about the aneurysm part of it, has not been uncommon.

FURTHER HISTORY

DR W. JASON MIXTER. The day following admission a subtemporal decompression was performed. A two and a half inch vertical incision was made in front of the right ear. Fibers of the temporal muscle were split and a moderate sized subtemporal decompression was done. The brain bulged strongly into the wound and no blood clot could be seen. The inferior horn was tapped in the temporal lobe and slightly bloody spinal fluid withdrawn. That fluid was much

less bloody than the fluid obtained by lumbar puncture previously. This did not seem to bring down the pressure very much. The posterior portion of the frontal lobe was then explored with the ventricular needle and a large amount of old fluid blood was evacuated. As I remember it, this was about three centimeters deep at the upper part of the subtemporal decompression. This brought the pressure down some where near normal. The needle was withdrawn, the tract was somewhat dilated and a small rubber drain was placed to the hemorrhagic cavity. The wound was closed in layers with silk.

The brain was placed in the cavity on account of the fact that there still seemed to be some blood oozing from the cavity and it seemed wiser to do that in order to prevent reaccumulation. The operation lasted approximately fifty minutes.

The preliminary diagnosis was spontaneous intracranial hemorrhage. The postoperative diagnosis was intracerebral hemorrhage with right subtemporal decompression and evacuation of clot.

That evening a lumbar puncture showed anochromic fluid. He was given intravenous glucose, but rapidly failed, did not regain consciousness and died.

FURTHER DISCUSSION

DR JAMES B. AYER. I want to say that if this is intracerebral hemorrhage it has not been usual to find aneurysm as the cause. The hemorrhages from aneurysms are usually at the base of the circle of Willis, which would indicate that we had a communication with the ventricles here. I do not think that we have as yet any reason to say we have any pathology back of it. One would think more of hypertension than of anything else, even though it be a young man. Trauma will do that sort of thing, give a perfectly typical history like this, and although we have no history of trauma, he may have had a trauma that has not been recognized and has given no outward evidence.

DR MIXTER. We had a pretty good history, and I do not believe there was any trauma. The blood seemed to be directly in the subcortical brain substance, very possibly near the ventricle, and definitely not in the subarachnoid space.

DR TRACY B. MALLORY. Under what conditions would you operate on a case of cerebral hemorrhage?

DR MIXTER. The reasons for operating in this case were to my mind about as follows. In the first place here was a man getting rapidly worse, whose pressure and symptoms were not controlled by lumbar puncture, with a definite localization to the right side. We did not know whether we were dealing with a subarachnoid hemorrhage, a subdural hemorrhage or a subcortical hemorrhage. I think that operation, craniotomy and exploration, under these cir-

circumstances are perfectly proper. I think the expectation of getting very much relief from evacuation of subcortical clot is not so good as when we have fluid blood on the surface. At the same time I see no reason why a subcortical clot which is causing marked compression might not be so operated upon with relief of symptoms. I should say, although I am not sure, that this lesion was probably in the neighborhood of the anterior cerebral artery or one of its branches.

DR MALLORY: One of the interesting points in this case, of course, is the blood pressure. It is known that an elevation of cerebrospinal pressure can produce an elevation of blood pressure, but not so definite a hypertension as this. Do you know the figures, Dr. Ayer?

DR AYER: No, but you are perfectly correct.

DR MIXTER: Another point is that the hypertension of increased intracranial pressure is increased in systole without much in diastole. This man had a diastolic of 100.

DR MATRICE FREMONT-SMITH: How much emphasis can be put on the absence of headache in a man who has a pretty good history and in whom you are trying to rule out the presence of subarachnoid hemorrhage?

DR MIXTER: I do not know. This came on rather suddenly. He went into coma pretty rapidly.

CLINICAL DIAGNOSIS

Subarachnoid hemorrhage

ANATOMIC DIAGNOSES

Cerebral hemorrhage

Cerebral arteriosclerosis

Multiple cerebral infarcts

Operative wound subtemporal decompression, right

PATHOLOGIC DISCUSSION

DR MALLORY: Our autopsy was limited to the head and Dr. Kubik will tell us about that.

DR CHARLES S. KUBIK: There is a hemorrhage which involves a large part of the right frontal and parietal lobes and has broken through into the lateral ventricle. It probably comes from one of the lenticulostriate arteries which may be seen entering the cavity resulting from the hemorrhage. The main cerebral arteries are thickened so that they do not collapse and there is some but not very extensive, atheromatous degeneration.

Microscopic sections reveal sclerosis not only of the main arteries and of the lenticulostriate and other small arteries within the substance of the brain but of the arterioles as well. There is further evidence of vascular disease in the form of tiny foci of degeneration in the cerebral cortex, the subcortical white matter and in the cerebellum.

DR MALLORY: I think with the anatomic findings in spite of the fact that we were limited to the brain that we are pretty safe in assuming that the underlying disease here was hypertension with marked arteriosclerosis and arteriolar sclerosis.

Dr. Mixter has just said that for at least five years previous to this acute episode the patient had not had a physical examination or a blood pressure reading, so we do not know how long he had had hypertension, very possibly for a considerable period.

DR VIETS: May I say just one word? It is possible now that we know the pathologic diagnosis that we should have paid a good deal more attention to the nicking of the vessels in the fundus in this young man. One would have expected to find, however, more signs of generalized arteriosclerosis than would be indicated by this single examination. The vessels of the retina often give a very good picture of the vessels of the cerebrum and that finding alone should have led us to suspect arteriosclerosis, and to have given more weight to that diagnosis.

THE SCIENTIFIC EXHIBITS OF THE ANNUAL MEETING

THE Scientific Exhibits of the Massachusetts Medical Society have always been a valuable part of the Annual Meetings, and in recent years they have been attracting a steadily increasing amount of interest. This is not strange when we realize that each exhibit offers in graphic form the concentrated results of months and years of someone's intensive work.

It requires no great gift of imagination, while standing before such an exhibit, to see the various specimens and charts dissolve, like something in a movie fadeout, and in their place to picture our colleagues in laboratories, operating-rooms and hospital wards, gradually collecting the bits of information which, pieced together, will make tomorrow's knowledge of disease. After this vision we stand appalled by the mass

of effort that can be crowded into one small booth.

The advanced program already published* gives promise of an unusually valuable collection of exhibits for the June meeting in Worcester. Some of them will later be shown at the Century of Progress in Chicago. They will all contain information which we as members of the medical profession cannot afford to pass by. The Society owes a great debt of gratitude to the exhibitors, not only for their scientific accomplishments, but also for their willingness to lay before us the results of their labors.

THE TYPHOID FEVER EPIDEMIC IN MAINE

FOR several years the opinion has been growing that typhoid fever no longer exists as a major menace to human life. Unfortunately our careless typhoid carrier may be the cause of a serious epidemic.

This was well shown in a report to this *Journal* by Dr. G. A. Coombs of 283 Water St., Augusta, Maine, who in addition to a large surgical practice is a part-time health officer. The report in the daily papers that the first case of typhoid fever in Augusta, Maine, was made ill by drinking water from the Kennebec river has not been proved, although suspected.

A brief report of the epidemic referred to is that the first case discovered was a boy who had been ill for about ten days before he was attended by a physician. The father of this boy took care of him and helped in the milking of cows on the dairy-farm. The milk was found to be distributed to thirty-seven families and two grocery stores, all being in the French section of the city.

Because of the likelihood of many infected persons, free anti-typhoid inoculations were provided for the whole city. In order to carry out this plan, nurses and a physician were provided by the State and during fifteen days more than 7,000 people were given anti-typhoid treatment at the free clinics. The physicians of the city gave the treatment to many private patients so that more than 8,500 persons were so treated. In addition all food handlers in the city, including milk dealers, were given physical examinations and specimens of urine and feces of all such were examined in order to check possible typhoid carriers.

About 65 cases with five deaths was the record of the epidemic. Seven of the cases and two of the deaths were in the family of the milkman where the original case occurred. Up to April 28 no new cases were reported. The health authorities were aided by the Augusta General Hospital where accommodations were provided for dealing with the patients.

Here is a brief recital of an epidemic of typhoid fever with its source recognized as promptly as possible under the circumstances, and fought efficiently. Of the way it was handled there seems to be no ground for criticism, but may not this episode be a strong argument for compulsory pasteurization of milk which may at any time be a serious menace to health if used in its raw state?

AN APPEAL FOR A SECTION OF DERMATOLOGY AND SYPHILOLOGY

On page 1136 there appears an appeal for the formation of a Section of Dermatology and Syphilology of the Massachusetts Medical Society.

Section 5 of Chapter IV of the By-Laws of the Society provides that, "The Council may vote to establish Sections for the consideration of scientific papers at the annual meetings of the Society and shall appoint the first chairman and secretary of a new Section so established."

This appeal which is signed by ten Fellows of the Society if presented at the Council meeting, merits consideration.

Intimation that the State Department of Public Health is also favorably disposed to the creation of this Section, lends weight to the movement.

Even though there have been expressed opinions favorable to curtailing the section activities in favor of general meetings, thereby eliminating competition regarding the conflicting time of different sections, this letter signed by prominent dermatologists must be given due consideration.

THE DOCTORS WELCH OF NORFOLK

BY HARVEY CUSHING

Over the river, on the hill,
 Lieth a village, white and still
 All around it the forest trees
 Shiver and whisper in the breeze
 Over it sailing shadows go,
 Of soaring hawk and screaming crow,
 And mountain grasses, low and sweet
 Grow in the middle of every street.

Over the northerly part of Litchfield County in Connecticut sprawl the rugged and heavily wooded foothills of the Berkshires, and in early May they are possibly even more lovely than when the first frosts of late September have suddenly turned to crimson the swamp maples of their lower valleys. But whatever the time of year, no part of Litchfield County is more quietly satisfying than the township of Norfolk which must have changed scarcely at all since Hopestill Welch decided to settle there one hundred and sixty-two years ago.

If the beauty of the countryside is thus felt by the casual visitor, how much more deeply must those feel who, born and bred in Norfolk village, have roamed the neighboring hills, fished the streams, and swum the ponds in boyhood days. And so the great grandson of this Hopestill Welch, though in the course of his eighty-four years he had wandered far and attained world renown, never lost his affection for the place of his birth and requested that it also be his place of burial just as it had been of his medical forbears.

Norfolk village, having been protected against the vandalism of modern days, has lost none of its old-time charm. Many of the villagers who have moved away and prospered have regularly returned to pass the summer on some of the nearby hillsides, but the village itself has changed but little. Loving hands have kept it trim and neat. The village green with its magnificent trees, its typical New England meeting-house and town hall is the same as always, and so too is the original village "burial-yard" laid out in 1757 as God's Acre.

Behind a low stonewall just beyond the last of the houses on the road to Canaan it lies inconspicuous to passers-by, on the lower slope of Haystack Mountain where it borders on the brook. In the shadow and solitude of great trees the headstones are scattered in groups as though they had accidentally grown there. No gravel walks, no artificial planting and regimented narrow plots have been needed here though the original acre has been considerably extended.

Whatever may have happened to the many from Norfolk who joined in the great migration to the New North-West—as did ten of Hopestill Welch's thirteen children—one gets the feeling that those who stayed behind must have lived to a great age else there would by this time be

more crowding in this one hundred and sixty square perches of land. Norfolknians while not boastful have good reason to take pride in the proverbial longevity of their people which is not surpassed or equalled by any other community in New England. In the space of two years not so very long ago, six persons died there whose average age was over ninety-three. Compared to this the Welches, as we shall see, mostly died young—in their early eighties, and it was a family tradition that they would be likely to keep going in perfect health just that long and no longer.

On this particular May fourth of 1934 with the countryside glistening after a warm Spring rain, the early afternoon sun struck across the hillside lighting up the feathery pink blossoms of the maples, the delicate early green of willows and birch, and the tufted white blossoms of an occasional shadblow, set off against the dark hemlocks and the brilliant green of the Spring turf, made it clear that the season had come to cast for speckled trout.

There is a touch of sadness and melancholy about Autumn which would seem the more natural time of year for an old man to die. But so far as anyone could ever tell, sadness and melancholy were moods of which he was incapable and it was as though he whose youthful spirit and reactions so belied his years had deliberately waited for Spring—waited at least as long as he could, for the season has been delayed by the hard winter and the venerable elms have not as yet burst their winter buds.

One such giant has come almost to envelop in protecting embrace the headstone of a certain Jerusha P —, who had been buried at its feet, evidently the wife of Captain John Porter who in 1793 came to be placed beside her. Another aged tree of the same kind once shaded the nearby knoll marked by a modest brownstone shaft where he the Welches and where a new grave has just been dug to hold the ashes of still another of them.

A few people had gathered at the knoll—his relatives and three or four others. Appropriate verses from Ecclesiastes were read by the local clergyman and followed by a simple prayer. Then two of his great-nephews who were at the same time his namesakes lowered the casket into its place. That was all—except for one incident.

In the small gathering was a frail little old lady whose many wrinkles could not conceal that she must once have been beautiful. She arose with some difficulty from the camp chair that had been provided for her and, refusing aid, walked over to where lay a spray of red roses she had brought and lifting them she placed them with her own hands beside the grave. Then turning away she said as to herself, "I shall now go." Only six months younger she was than this friend of her childhood, they

had long ago been playmates—perhaps, on her part, something more than that.

It was the same little old lady who four years before had been taken in a wheel chair all the way to Washington so that she might hear in Continental Hall what the President of the United States and other notables would have to say about her lifelong friend, and also what in return he would have to say for himself on that day when speeches in honor of his eightieth birthday were broadcast to all quarters of this country and abroad.

While this public celebration with its spontaneous outburst of affection was in its way a sort of canonization honors had been heaped upon this particular Doctor Welch throughout his life. He could not avoid them without being ungracious—and this he never was—but they left him unchanged in his simplicity. He always behaved on these occasions as though he were merely representing someone else—someone else who deserved the honor and for whom it was really intended.

It had been urged that the National Cemetery at Arlington was the proper place for him to be in view of his distinguished service during the War. He had merely volunteered on an April day in 1917 to help his friend the Surgeon-General, open his rapidly overwhelming mail, and the close of the War found him still there—much to his surprise and somewhat to his amusement—a Brigadier-General. But a military funeral with gun carriage firing squad the last post and all that, just because he had done his duty as he saw it would have been incongruous and unsuited to his real character and life. Public though much of it had come unsought to be. It was wholly consistent and typical of him that he should choose to rest where to the future passer-by he would be just another of the many Doctors Welch of Norfolk.

Even now should you happen to ask the aged apothecary in the village which of the Doctors Welch was the more celebrated, he would certainly say William Wickham the father of this William Henry. And should you venture to demur, knowing that William Wickham weary of compounding his own drugs had set him up in business some fifty and more years ago, he would be likely to reply:

"If you don't believe me just ask any middle aged person you may chance to meet up with for thirty miles around and see if they don't agree. Most of 'em will remember when they used to put a light in the window for him should he happen by in the dead of night. He was never known to send out any bills—pretended to forget that people owed him money and those who paid had to press it on him. There's his house just down the street—as it was when at the end of his seventy four years he left it to his successor—a good man too

though he could not stand the wear and tear so long as if he'd been a placid and good-humored Welch.

"It was in that house his son Willie was born and there's a tablet on it saving as much, but if you think the drinking fountain in front for thirsty horses coming up the hill, was put there in memory of your friend rather than for William Wickham his father, you make a great mistake. If you haven't forgotten your Latin, just go and read the inscription cut around its rim.

"And you will find just off the road the little house in which his father, Dr. Benjamin Senior, lived until he died at eighty-two, beloved like all the rest of them. It was his second wife, Elizabeth Loveland, a beautiful woman who lived to be eighty and was everybody's friend and known to every Sabbath-School boy in the town as 'Grandma Welch'—it was she who brought up the Dr. Welch you've just seen buried today, for his mother died when he was barely six months old.

"William Wickham wasn't the only one of old Dr. Benjamin's sons who took up medicine, there were four others who spent their lives within thirty miles of here—all men of the same kind and they are all buried together in the Acre. Asa was the eldest. He first started out in Tyringham but was invited to settle in Lee where he practised until his death. He was interested in public affairs—as indeed they all were for that matter—though he was the only one who happened to be sent to the State Senate. Benjamin Jr. was the next. He got his M.D. at Yale in 1823 and was in active practice for fifty-four years—first here for a time, then at Litchfield and finally at Salisbury. He became celebrated as a surgeon and there was a common saying hereabouts 'Don't give up hope before you've sent for Dr. Benjamin'.

"James was the third son. He got his degree at the old Berkshire School in 1830 and settled at Winsted where he built up a large practice in which he was active till he reached eighty, and what's more at least three of his sons became doctors. Then came William Wickham—the best of them all to my thinking. And after him the fifth and youngest was John Hopestill who also graduated at the Pittsfield school in 1848 and then practised in Salisbury, in Cornwall and in Norfolk till 1871 when he moved to Hartford where he finally drifted out of medicine into a manufacturing business."

So it would seem there must have been at least ten doctors in these three generations, all apparently men of very similar type good judges of people and good public servants, men able to instill confidence and win regard, all of them blessed with a rare capacity to gain and retain friendships with young and old all of them apparently men who were respected, admired and beloved. And then to follow the old apothecary's advice you go down the road and

find cut on the rim of the fountain erected in memory of your friend's father—the last of the Doctors Welch to pass his life wholly in Norfolk—what might be no less appropriate to William Henry his son

FONS SUM SOLATI TALIS ET IPSE FUIT

MISCELLANY

CONGRATULATIONS TO DR ELLIOTT P JOSLIN

According to reports in daily papers, Mrs Mabel H McCarthy of Buffalo provided in her will for a bequest for five thousand dollars to Dr Joslin to be used in promoting the work at his camp for the treatment of diabetic children

THE GREATER BOSTON MEDICAL SOCIETY CHANGES ITS NAME

Under the title of the New England Association of Jewish Physicians adopted by the Greater Boston Medical Society the old title was discarded at the Annual Meeting of this body

The officers elected are

President Dr Herrman L Blumgart.

President Elect Dr Harry C Linenthal

Vice President Dr Henry Kontoff

Treasurer Dr Max Ritvo

Secretary Dr David B Stearns

MASSACHUSETTS DOCTORS ELECTED TO FELLOWSHIP IN THE AMERICAN COLLEGE OF PHYSICIANS

On April 16 at the meeting of the American College of Physicians, in Chicago, Drs Horace K Boutwell of Brookline, Felix Percy Chillingworth of Boston, and Robert Sterling Palmer were elected to fellowship

THE FORSYTH DENTAL INFIRMARY

To a reader of the Nineteenth Annual Report of the Forsyth Dental Infirmary, interesting facts are apparent.

This institution is an important agent in promoting the hygiene of children, and occupies an important position in preventive medicine

It is within a comparatively few years that the treatment of oral diseases and defects of the teeth have been adequately recognized as important factors in preventive and therapeutic medicine, and beyond these obvious functions of dealing with disease, scientific dentistry in the field of orthodontia has a recognized relation to the psychology of childhood because the correction of deformities promotes self-esteem and confidence in the child

The attitude of the dental profession toward the Forsyth Infirmary is reported to be cordial, which is commendable John Hamilton Forsyth and his brother George Henry Forsyth have made a great contribution to the well being of children in co-operation with the George White Health Units

AN ENDORSEMENT OF DR TIMOTHY LEARY'S FINDINGS

At a meeting at Utica, New York, of the New York State Medical Society Dr Harrison S Martland, of Newark, New Jersey, Chief Medical Examiner of Essex County, said in reporting cases of sudden deaths, "As we grow older, I believe we eat too many dairy products I agree with Dr Timothy Leary of Boston that we eat too many foods high in cholesterol content as we pass the 40 mark. By that I mean butter, eggs, cream and other dairy foods"

MORTALITY RATES

Telegraphic returns from 86 cities, with a total population of thirty seven millions for the week ending May 5 indicate a mortality rate of 120 as against a rate of 112 for the corresponding week of last year The highest rate (193) appears for Nashville, Tenn., and the lowest (50) for Flint, Mich The highest infant mortality rate (167) appears for El Paso, Texas, and the lowest for Fort Worth, Texas, Louisville, Ky, Miami, Fla, Tacoma, Washington, and Wilmington, Del, which reported no infant mortality

The annual rate for 86 cities is 125 for the eighteen weeks of 1934, as against a rate of 120 for the corresponding period of the previous year

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS) FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS OF 1934 AND 1933

	Week ending		First 18 weeks	
	May 5, May 6,		1934	1933
	1934	1933		
Total deaths	164	130	2,824	2,474

A RADIO MESSAGE PREPARED AND SPONSORED BY THE COMMITTEE ON PUBLIC EDUCATION OF THE MASSACHUSETTS MEDICAL SOCIETY FOR THE DEPARTMENT OF PUBLIC HEALTH

THE RISE OF PUBLIC HEALTH CONSCIOUSNESS

BY ELEANOR J MACDONALD, A.B.*

The evolution of the present public health movement covers a period of about three thousand years It has advanced with the progress of civilization and comprises the ideas and accomplishments of many men of many ages The progress in the past seventy five years far exceeds that of the previous centuries, but the contributions of the Hebrew, Greek and Roman Periods and also of the Middle

*Statistician Division of Adult Hygiene Massachusetts Department of Public Health.
Station WEEL 1 15 P.M. January 19 1934

Ages have formed part of the basic structure in this development.

The beginnings of public health are chronicled in the Old Testament. The Mosaic rites furnished real public health precepts. A definite code for hygiene comprising diet, sex hygiene and avoidance of unclean objects is clearly defined. Directions are given for the segregation of the sick and the use of disinfection to prevent the spread of contagious disease. These public health measures were incorporated in the fundamentals of the religion, and high priests were guardians of the body as well as of the soul.

The contribution of Greece to public health was the attempt in Sparta to develop a physically perfect race. The humanitarian instinct of caring for the sick was not popular with them. Physical fitness was the desired end. All weak children were thrown into a cave on Mount Taygetus to die. The stronger ones were given a vigorous training in athletics and were subjected to the hardships of scanty clothing, plain food and stern discipline. The product of this training was characterized by Woodrow Wilson in 'The State' as 'a fine soldiery, and noble soldiers' mates, shapely sturdy women and lithe laconic men.

The beginnings of sanitation were found in early Rome in the water supplies, sewerage systems and methods for nuisance prevention. According to Frontinus, Water Commissioner of the City of Rome in the first century. From the Foundation of the city for 441 years (or until 313 B.C.) the Romans were content with the use of waters which they drew either from the Tiber or from wells or from springs. Springs have held down to the present day the name of holy things and are objects of veneration having the reputation of healing the sick, as for example the springs of the Prophetic Nymphs of Apollonia and of Juturna. But there now runs into the city the Appian aqueduct.

The early sewers were for drainage purposes and did not carry human excreta. In fact sewers for human excreta did not make an appearance until the nineteenth century. Later sanitarians were to improve on these early efforts, but to Rome belongs the beginning of sanitation.

Man has always been prone to consider that thing unimportant of which he has no certain knowledge. This can be the only explanation then for the period between classical antiquity and the Renaissance having been called the Dark Ages for so long. In architecture and art, it is in many respects still unequalled. In public health the classical ages left us with our first ideas of physical perfection and a sanitary and hygienic code. The first records of the Renaissance discuss accepted incidents such things as hospitalization of the sick, various types of surgery, numerous medical schools, quarantine for ships from plague-infested ports and detailed if erroneous books on anatomy.

To quote Garrison in his History of Medicine

"The growth of the Christian virtue of compassion towards weakness and suffering, and the more elevated and enlarged conception of the position and mission of women which grew out of it, led to new departures in medicine along untried paths, particularly in nursing the sick and in erecting hospitals everywhere for their care. Only idle bigotry could affirm that Pope and Emperor did not do a great deal for medicine in the advancement of good medical legislation, in the chartering and rebuilding of the medieval universities, in the great hospital movement of the middle ages, and in the encouragement of individual medical talent in many cases."

During this period the hygienic principles first noted by the Hebrews were improved. Many of the rules given in the "Regimen," a handbook of the medical school of Salerno, are good hygienic practice today.

An English translation of one of these advices follows:

'If thou to health and vigour wouldst attain
Shun weighty cares—all anger deem profane
From heavy suppers and much wine abstain
Nor trivial count it, after pompous fare,
To rise from table and to take the air
Shun idle noon-day slumber, nor delay
The urgent calls of Nature to obey
These rules if thou wilt follow to the end
Thy life to greater length thou mayst extend."

While hygiene advanced, sanitation was neglected. In a letter Erasmus said concerning the condition of the English household of the sixteenth century: as to the floors they are usually made with clay covered with rushes that grew in the fens which are so slightly removed now and then that the lower part remains sometimes for twenty years together and in it a collection of spittle, vomit, urine of dogs and men, beer scraps of fish and other filthiness not to be named.

The first mention of isolation occurred in the ancient Hebrew texts but its extensive application came about in the Middle Ages. Leprosy, bubonic plague, syphilis and smallpox were epidemic during this period and strenuous efforts were made to curb them by quarantine and isolation. The success was most marked in leprosy. Nineteen thousand hospitals for lepers were built and the disease gradually died out in Europe. The results were less apparent with the bubonic plague. In the fourteenth century the black death destroyed one-fourth of the population of Europe. Quarantine was instituted against ships from the plague districts but little attention was given to rats. This would account for the imperfect effect of control of this disease.

AN APPEAL FOR A SECTION OF DERMATOLOGY AND SYPHILOLOGY

Editor, *New England Journal of Medicine*

The growth of interest in dermatology and syphilology in the past twenty five years has been striking. This is manifest in the number of societies which now exist, in the steady increase in attendance at these meetings and perhaps most of all, in the fact that it has been deemed important to establish a national board known as the American Board of Dermatology and Syphilis, which issues a certificate of fitness to such only as can pass its rigid examinations and searching investigations.

There are four societies with which Massachusetts dermatologists are affiliated. First, there is the New England Society whose membership is largely composed of Massachusetts men. Then there is the Atlantic Dermatological Conference which originated in Boston and now includes societies from Montreal to Washington. Thirdly, there is a large section of the A. M. A., and fourthly, the American Dermatological Association.

As to the attendance at these various societies to which the Massachusetts dermatologists and syphilologists belong, we need only to study the New England Society to obtain a picture of them all. Starting in 1915 with seventeen members, the New England Society to-day numbers seventy five active members with several honorary members in other states.

Hospitals and medical schools, also reflect the growth of interest. The country over the clinics for dermatology and syphilis are as large and in some instances larger than those for medicine and surgery. (Abroad, three and four hundred bed hospitals devoted solely to dermatology and syphilis are no rarity. In this country though the number of hospital beds is steadily growing we are still behind.)

Finally nine state societies have created Sections for Dermatology and Syphilis which have invariably been great successes.

For these reasons the time has come for the Massachusetts Medical Society to have a section of Dermatology and Syphilis. With such a section in existence as a part of the Society much will be added to the program of the Annual Meeting which must concern and interest the general practitioner. We, therefore, ask the Council of the Massachusetts Medical Society to establish such a section at its next meeting in order that its educational work

may begin at the Annual Meeting of the Society in 1935

CHARGES FOR THE MAINTENANCE OF THE MIDDLESEX SANATORIUM

May 17, 1934

Editor, *New England Journal of Medicine*

The letter from Dr. Blaisdell in the March 23 issue interested me for at the present time I happen to be on the Board of Health of Lincoln in the same county as Winchester, and we must bear our proportionate charge for the maintenance of the Middlesex Sanatorium, the institution which Dr. Blaisdell criticizes.

In the first place, your correspondent states that the town of Winchester was never consulted about building this Sanatorium. That, of course, is an erroneous statement, for the Hospital was built by a mandatory Act of the State Legislature passed in 1928, Chapter 369, and approved by the Governor June 5, 1928. The town of Winchester has its representatives in the Legislature.

The original assessment to the town of Winchester was \$60,552.72. Of this, Winchester paid \$552.72 in 1932 and elected to have the balance financed by bonds to run for fifteen years, \$4,000 maturing each year. Winchester has made two payments on the principal. The interest paid in 1933 was \$3,191.39, and for 1934 it was \$2,293.74. Obviously as the principal is paid the interest decreases considerably. This is another inaccurate statement by your correspondent, for the town of Winchester is not paying interest at five per cent on \$60,000.00.

Again he does not explain how he obtains the charge for maintenance, \$4,553.80. The facts are that \$926.72 of this amount was due the Commonwealth from the county over a period of years, and last year by authority of the Legislature (Chapter 331 Acts of 1933) the long standing bill was apportioned to the various towns and this was Winchester's share. In no way should this be added to the maintenance charge.

The item of \$1,655.50 which is for the care of patients for 135 weeks, appears to be the one correct statement in the letter. I would call attention to a further inaccuracy in that your correspondent did not state that the town of Winchester received \$689.99 from the State as a subsidy for the tuberculous patients.

There may of course be an honest difference of opinion as to whether the original cost of the insti

tution should be counted in the weekly cost of the patient. Personally, I do not think that it should. If it is, your correspondent is again wrong in his estimate of the weekly cost. The total should be \$10 886 33, obtained by adding principal paid \$4 000 interest paid \$2,293 74, maintenance \$3,627 08 and care of patients for 135 weeks \$1 655 50 and subtracting the subsidy the town received of \$689 99. This will give a charge per week of \$80 64. I do not feel that the principal and interest should be included in this total. If they were eliminated the cost last year to the town would be \$4,592 59 and the cost per week \$34 01.

It may be of interest to know what Lincoln paid because of this county hospital. Our original assessment was \$5 900 01 which we paid at once. In 1934 we were assessed \$430 20. We have not yet had a patient in the hospital.

The care and management of tuberculosis is a community problem and in my opinion cannot be looked after satisfactorily by the general practitioner. When one realizes that this Sanatorium gives complete care by specialists in tuberculosis, has a sufficient number of trained nurses, dietitians and a splendid plant, to me it is remarkable that the cost to the county per week is so small.

In addition to the regular care and treatment, special service is given to suitable patients. All forms of collapse therapy are in use and it is interesting for the profession to know that at the end of 1933 62½ per cent of the 256 patients then at the Sanatorium had received some form of collapse therapy.

Another important point to be remembered is that the Sanatorium operates an outpatient department where diagnostic service is given without cost to patients of the physicians in the district. Reports of x-ray examinations, tuberculin tests and physical examinations are promptly rendered to the physicians of the county sending their patients there for examination. In 1933 the outpatient department examined 2 044 patients. Further the Sanatorium sends out members of its staff to conduct clinics at the following places: Ayer Memorial Hospital which serves the eleven towns of the Nashoba health district, Newton Hospital for the City of Newton and Lawrence Memorial Hospital for the city of Medford.

The waiting list of the Sanatorium is regrettable but is it not a tribute to the high standard of the service given by the institution and the desire of patients to go there? Not infrequently when urgent cases have applied for admission and have been referred to other institutions, they have elected to wait until they could get into the Middlesex Sanatorium.

The trustees held a meeting a short time ago at the Sanatorium to tell the county that there was a greater demand for beds than they could supply and at the present time they are trying to secure permission from the Legislature for an addition of approximately 135 beds to meet this greater demand for treatment.

It is without doubt expensive to care for tuberculosis properly, but it is a disease the prevention of which is important to the entire community and because of that I believe the work in eradicating tuberculosis should be supported in every possible way and careless criticism should not be made.

ROBERT L. DENORMANDIE.

Lincoln Mass

RECENT DEATHS

CHURCHILL—ALICE SYMONDS CHURCHILL, M.D., (reported in the *Boston Herald* as Alice A. Symonds), formerly of Haverhill, died in a hospital at Yarmouth, Nova Scotia May 14, 1934. She was born in 1860. She graduated from the Massachusetts General Hospital Training School for Nurses and later from the Tufts College Medical School in 1899.

She practiced in Haverhill for several years and served on the staff of the Hale Hospital.

In 1918 she did commendable work in the influenza epidemic.

She left Haverhill about twelve years ago and since then has spent her winters in Florida.

She joined the Massachusetts Medical Society in 1900 and resigned in 1906.

WEBBER—CHARLES SUMNER WEBBER, M.D. of 35 Front Street, Weymouth, Massachusetts, died suddenly May 16, 1934. He was born in 1897. He was a graduate of Boston University School of Medicine and later of the Medical School of Tufts College and was on the faculty of the Medical School of Boston University. He joined the Massachusetts Medical Society in 1926, and was a Fellow of the American Medical Association. He is survived by his widow, a son, a daughter, his mother and a brother.

COUTURE—MICHAEL HORATIUS COUTURE, M.D., of 58 Western Avenue, Lynn, Massachusetts, died in that city May 16, 1934. He was born in St. Hyacinth, Quebec, in 1872. He graduated in medicine from the University of Montreal Faculty of Medicine in 1893. Previous to practicing in Lynn he practiced in Montreal up to 1899.

Dr. Couture was one of the organizers of the Franco-American Society in Lynn and a member of the St. Jean Baptiste Church. He is survived by a sister, Miss Mary Couture of Coatcook, Quebec.

CHARGES FOR THE MAINTENANCE OF THE MIDDLESEX SANATORIUM

May 17, 1934

Editor, *New England Journal of Medicine*

The letter from Dr. Blaisdell in the March 23 issue interested me, for at the present time I happen to be on the Board of Health of Lincoln in the same county as Winchester, and we must bear our proportionate charge for the maintenance of the Middlesex Sanatorium, the institution which Dr. Blaisdell criticizes.

In the first place, your correspondent states that the town of Winchester was never consulted about building this Sanatorium. That, of course, is an erroneous statement, for the Hospital was built by a mandatory Act of the State Legislature passed in 1928, Chapter 369, and approved by the Governor June 5, 1928. The town of Winchester has its representatives in the Legislature.

The original assessment to the town of Winchester was \$60,552.72. Of this, Winchester paid \$552.72 in 1932 and elected to have the balance financed by bonds to run for fifteen years, \$4,000 maturing each year. Winchester has made two payments on the principal. The interest paid in 1933 was \$3,191.39, and for 1934 it was \$2,293.74. Obviously as the principal is paid the interest decreases considerably. This is another inaccurate statement by your correspondent, for the town of Winchester is not paying interest at five per cent on \$60,000.00.

Again, he does not explain how he obtains the charge for maintenance, \$4,553.80. The facts are that \$926.72 of this amount was due the Commonwealth from the county over a period of years, and last year by authority of the Legislature (Chapter 331, Acts of 1933) the long standing bill was apportioned to the various towns, and this was Winchester's share. In no way should this be added to the maintenance charge.

The item of \$1,655.50 which is for the care of patients for 135 weeks appears to be the one correct statement in the letter. I would call attention to a further inaccuracy in that your correspondent did not state that the town of Winchester received \$689.99 from the State as a subsidy for the tuberculous patients.

There may, of course, be an honest difference of opinion as to whether the original cost of the insti-

ESSEX NORTH DISTRICT MEDICAL SOCIETY

The ninetythird annual meeting of the Essex North District Medical Society was held at the Andover Country Club on Wednesday May 9 1934, at 12 30 P M Dr Parr, vice-president, presided in the absence of Dr Coffin A steak dinner was served at 12 30 followed by the business meeting

The records of the previous meeting were read and approved

On motion of Mr Burnham it was voted that the Society pay seventy five cents for each member (half the cost of the dinner)

The treasurer's report was read and accepted by the Society

The report on the Committee on Permanent Funds was read by Dr G S Allen showing a total on deposit at present \$1553 32, with a balance due the Permanent Fund from the frozen assets at the First National Bank in Haverhill of \$153 64

Resolutions on the death of Dr Merrill of Lawrence were read by Dr Sargent and it was moved that they be spread upon the records and a copy sent to the family

The report on the death of Dr McGauran was read by Dr McAllister and it was voted that this be inscribed on the records and a copy sent to the family

The report of the Public Relations Committee was

submitted by Dr Bagnall and was accepted as a report of progress

Dr Sweetsir, chairman of the nominating committee, submitted the nomination of officers for the ensuing year and it was unanimously voted that the secretary cast one ballot for the list as submitted, which list is appended below

The president then introduced Dr L M Hurxthal who showed two very instructive reels of moving pictures manifesting very clearly in a diagrammatic way the mechanism of heart action through its conducting paths and parallel, with these diagrams the part of the electrocardiogram corresponding with each part of the cycle

Dr L E Phaneuf, of Boston, was then introduced and, with the assistance of lantern slides, demonstrated and discussed some of the more common lesions with appropriate office treatment, in the gynecological field. Dr John Sprouli of Haverhill was then introduced and discussed in a very practical way the diagnosis and management of angina pectoris

The meeting was adjourned at 4 30

PHI DELTA EPSILON FRATERNITY

The Phi Delta Epsilon Fraternity of the Boston University School of Medicine held its meeting in the Evans Memorial Auditorium on Monday, April 23, 1934 Dr Alexander S Begg presided

The first speaker was Dr Lewis M. Hurxthal of the Lahey Clinic, who presented a very interesting discussion of 'Myxedema, Hypometabolism and Blood Cholesterol' Several instructive cases were presented and illustrated by means of lantern slides

- 4 Fracture of neck of femur—nail operation Dr John W O'Meara.
5 Trichiniasis simulating surgical conditions Dr John M. Fallon
6 X ray diagnosis—Kidney Dr A E O'Connell
7 Pathological demonstration Dr William Moran

WORCESTER CITY HOSPITAL

The program of clinics to be given at the Worcester City Hospital, Monday, June 4, 1934 (the first day of the annual meeting of the Massachusetts Medical Society) has been amended as follows

Participating in the Surgical Section, in addition to Dr F H Lahey, who will present peptic ulcers, the following names have been included

Dr G E Haggart, presenting fractures, Dr H M Clute, presenting gall stones, Dr R B Cattell, presenting cancer of the colon and rectum, and Dr L M Huxthal, presenting thyroidectomy and myxedema

A complete program will be distributed at the meeting

REPORTS AND NOTICES OF MEETINGS

THE NORFOLK DISTRICT MEDICAL SOCIETY

The Annual Meeting of the Norfolk District Medical Society was held in the Hotel Kenmore, Boston, on the evening of May 8, 1934. The business meeting was called to order by Dr Begg, the President, at 6 15 P M. Minutes of the previous meeting were read and accepted. Report of the Treasurer was read and accepted. Reports of various committees were read and accepted. The Nominating Committee's List for 1934-1935 was then read and the Secretary was instructed to cast one ballot for the list as read. The ballot was so cast and the following officers were declared elected

President Cadis Phipps, Brookline

Vice President Leighton F Johnson, Norwood

Secretary Frank S Cruickshank, Brookline

Treasurer George W Kaan, Sharon

Commissioner of Trials H F R. Watts, Dorchester

Nominating Councilor T J Murphy, Roxbury
W A. Griffin (Alt), Sharon

Censors H K. Boutwell, Brookline E P Rugles, Dorchester George W Winchester, Milton
Herbert L Johnson, West Roxbury, Maurice Gerstein Roxbury

Councillors H L Babcock, Dedham, Karl R Bailey, Jamaica Plain Henry Baker, Dorchester, F G Balch, Jamaica Plain Hollis Batchelder, Dedham A S Begg West Roxbury, David D Berlin, Brookline David N Blakely, Brookline H K Boutwell, Brookline, Walter L Burrage Brookline, F S Cruickshank Brookline S F Curran, Dorchester David G Eldridge Dorchester, A. Watts, Dorchester

At the close of the business meeting it was announced that a letter of commendation was received by the officers in connection with the work of the Legislative Committee of this Society expressing appreciation of the work of this committee with particular reference to its activities in relation to Senate Bill No 162

A standing vote of thanks was accorded the officers of the Society and the Committees for their work during the past year

After the transaction of certain incidental business this section of the meeting was adjourned

An excellent dinner was enjoyed in the Crystal Room of the Hotel and following this the members and guests enjoyed an extremely interesting illustrated lecture entitled "The Romance of News Gathering," by Mr Alton Hall Blackington, photographer for the *Boston Herald*

FRANK S CRUICKSHANK, M D, *Secretary*

lost. The slightest injury to the eyes in cases of exophthalmos exposes them to infection and subsequent complete destruction. In operating upon a patient with exophthalmos therefore extreme care should be exercised in the protection of the eyes.

The subject of iodine in hyperthyroidism was next discussed. The administration of iodine leads to remarkable changes in the hyperplastic thyroid. The colloid is increased, the iodine content of the dried gland is increased and the epithellum is changed from the typical columnar type of the hyperplastic gland to a low cuboidal. Marine believes that the iodine causes an accumulation of colloid within the follicles and this through the agency of increased pressure causes a regression of the hyperplasia. Patients become refractory to the influence of iodine after this drug has been administered for about two months. For this reason physicians should not administer iodine to patients with hyperthyroidism if operation is planned for the near future. The administration of iodine should be left in charge of the surgeon.

Dr Lahey discussed the group of patients which he has termed thyrocardiac. These are patients with hyperthyroidism and either auricular fibrillation or cardiac decompensation. The condition results from the overloading of a previously damaged heart by overactivity of the thyroid. The mortality from operations on thyrocardiacs has been about 4.25 per cent. About 97 per cent of patients have been permanently relieved of decompensation. Follow up has shown, however, that the blood pressure continues to have a rising tendency in spite of operation.

The speaker next described the condition of intra-thoracic goiter and illustrated the clinical picture and x-ray findings by lantern slides. About eight per cent of over 12,000 goiters at the Lahey Clinic have been intrathoracic. Symptoms of dyspnea and choking are prominent in this condition and most apt to come on at night when the bronchi are not kept so well cleared as during the daytime. The mortality from operation in this type of goiter has been only two per cent.

Dr Lahey ended his talk with a consideration of tumors of the thyroid in which he brought out interesting points both in diagnosis and treatment. About 96 per cent of thyroid carcinomata arise from fetal adenomata. Metastasis of the histologically benign adenoma was explained by the fact that these tumors grow into veins and so are transported elsewhere in the body. The location and typical appearance of lateral aberrant thyroids were discussed and their relation to malignancy was emphasized.

An excellent discussion of the subjects presented was given by Dr Allan Winter Rowe. He pointed out the numerous factors which influence the basal metabolic rate so as to make the determination unreliable. The blood cholesterol level may well be a better index of thyroid deficiency. Even this however may be hardly more than a rough index. Dr Rowe said that the true significance of blood constit-

uents will be realized only when the laboratory sciences have progressed to such a degree as to enable us to interpret the various elements in terms of each other. Drs Hurxthal and Lahey answered several questions which had been asked during the course of the discussion.

NEW ENGLAND MEDICAL SOCIETY

The semi-annual meeting of the New England Medical Society will be held in the Evans Auditorium of the Massachusetts Memorial Hospitals, 80 East Concord St., Boston on Thursday, May 31, at 8 15 P.M. The speaker of the evening will be Dr Edward W. Archibald of Montreal, Professor of Surgery, McGill University Faculty of Medicine. His subject will be 'The Aetiology and Treatment of Recurring Subacute Pancreatitis' (with lantern slides). Discussion by Drs Charles T. Howard, Daniel F. Jones, Richard H. Miller, William R. Morrison and Lester R. Whitaker. All physicians interested in this subject are invited to attend this meeting.

RUDOLPH JACOBY, M.D., *Associate Secretary*

AMERICAN ASSOCIATION FOR THORACIC SURGERY

The seventeenth annual meeting of the American Association for Thoracic Surgery will be held in Boston on May 31, June 1 and 2. A program of papers on thoracic surgery and allied subjects will be given on Thursday and Friday in Building C Amphitheatre at the Harvard Medical School. On Saturday morning programs will be provided at the Massachusetts General Hospital, the Peter Bent Brigham Hospital and the New England Deaconess Hospital on thoracic disease.

Owing to a limited seating capacity a large portion of the Amphitheatres must be reserved for members of the Society and their out-of-town guests. However, it is hoped that there will be adequate space to enable local members of the profession particularly interested in this field to attend the sessions.

ALUMNI LUNCHEON

Massachusetts Alumni of University of Maryland Medical School, Baltimore Medical College, College of Physicians and Surgeons, Baltimore.

Date—Tuesday, June 5th

Time—12 30 P.M.

Place—Hotel Bancroft, Worcester

Reservation should be made through Dr W. B. Davidson (1917), 36 Pleasant St., Worcester.

AMERICAN PROCTOLOGIC SOCIETY

CLEVELAND MONDAY AND TUESDAY, JUNE 11-12, 1934

Headquarters: Hotel Cleveland

Arrangements: T. E. Jones, Cleveland; C. C. Neckling, Pittsburgh.

Regular and orthodox practitioners, members of the American Medical Association and not affili-

It was pointed out that the basal metabolic rate does not parallel the degree of thyroid deficiency, and cases are frequently encountered in which the deficiency is not clinically apparent and the basal metabolic rate is equivocal. It is especially in these cases that a determination of the blood cholesterol is helpful in so far as it is an indicator of thyroid deficiency. It is also of great value in determining whether a patient needs substitution therapy after subtotal thyroidectomy.

Dr Hnrxthal illustrated five cases of hypopituitarism from chromophobe adenomata. In these cases the basal metabolism varied from minus 18 to minus 37 but there was no elevation of the blood cholesterol. For this reason it is unlikely that the lowered metabolic rates in these cases were due to a secondary depression of the thyroid. Normal cholesterol values were found in spite of lowered basal metabolism in five cases of obesity, two cases of Addison's disease, and several cases of hypometabolism from other causes. In conclusion Dr Huxthal discussed the advantages of the blood cholesterol as a clinical aid in the diagnosis of thyroid deficiency states.

Dr Frank H. Lahey next discussed "Hyperthyroidism, Its Diagnosis and Management." By means of lantern slides he showed patients, illustrating the different forms of the disease. The first case was that of a young girl with extraordinarily prominent signs of hyperthyroidism. The picture was one of typical "frozen fright"; there was such marked exophthalmos that considerable difficulty was experienced in attempting to keep the lids from slipping back behind the eyeball, and the other classical signs of Graves' disease were present. There was no apparent enlargement of the thyroid gland. The speaker emphasized the fact that the disease is exactly the same in young and adults. Children, however, have a tremendous capacity for reacting to intoxications of any sort. Hence it may become difficult to tell whether a given clinical picture, such as fever, elevated basal metabolic rate, etc., is due to the intensity of the disease process or to the exaggerated way in which children react to the intoxication. For this reason two exceptions are made in the treatment of hyperthyroidism in children:

- 1 One-stage subtotal thyroidectomy is to be avoided because of the violent reaction that children may have postoperatively.

- 2 Children, unlike adults, need the products of thyroid activity for growth and development so that less thyroid is removed at operation than in adults.

Dr Lahey next described an interesting group of cases of what he has called "Apathetic Hyperthyroidism." The underlying condition is essentially identical with that of typical Graves' disease, but the difference in the clinical pictures is due to the fact that the former occurs in older individuals who not only react differently to the intoxication but are very apt to have a long standing burned out process. In these cases one finds no anxiety or tension. The picture is rather one of apathy. Instead of

warm, moist, flushed skin of the activated case one finds a cool, dry, pigmented, wrinkled skin. The cause of the pigmentation is not understood but it disappears after operation. The basal metabolic rate in these patients is only moderately elevated. There is a tachycardia, but the typical pounding heart found in young persons is absent. The diagnosis of apathetic hyperthyroidism is made by the presence of an unexplained slightly elevated basal metabolism, a tachycardia, a history of loss of weight over a long period of time and no marked myasthenia.

The speaker then described Thyroid Crisis and its management. The clinical picture and the results of treatment were very well illustrated with lantern slides. Patients have crises when a maladjustment occurs between the food intake and the fuel required to satisfy the increased basal metabolism. The imbalance is aggravated by vomiting and diarrhea which are prominent symptoms. Once the state of thyroid crisis has set in, treatment is difficult, but if the condition is recognized before it is fully established it responds to treatment quite satisfactorily. For early diagnosis, the following points should be borne in mind:

- 1 A rise in pulse rate day after day for no obvious reason.
- 2 Unexplained vomiting and diarrhea.
- 3 Signs of irrationality.
- 4 The development of an infection of any kind.

Any of the above signs should make one suspect impending crisis in hyperthyroidism and is an indication for the institution of immediate treatment. Dr Lahey stressed the use of constant intravenous glucose in saline in the management of crisis. It is best to cut down on the vein and tie in an indwelling intravenous needle. The five per cent glucose solution is run in at a rate of 40 to 60 drops per minute night and day for as long as necessary. The speaker cited one case in which this was done for eleven days.

The consensus has been in the past not to operate upon patients for a considerable time after crisis. Dr Lahey pointed out that this idea has been erroneous. He advised vigorous pre-operative treatment with a high carbohydrate diet after the crisis has been passed. This is followed in two or three weeks by removal of half the thyroid which prevents the patient from returning into crisis. After about six weeks the operation for subtotal thyroidectomy is completed.

The treatment of the eyes in hyperthyroidism is very important. One case was illustrated in which exophthalmos developed after a condition of myxedema had set in with a basal metabolic rate of minus 25. Exophthalmos is due to a myxomatous infiltration of the extrinsic eye muscles so that the orbit is unable to accommodate all the ocular tissues. The logical treatment is therefore to decompress the orbit and this is accomplished by removing the roof of the orbit on each side a neurosurgical procedure. Dr Horrax has done this operation in a few cases and thus saved eyes which would certainly have been

lost. The slightest injury to the eyes in cases of exophthalmos exposes them to infection and subsequent complete destruction. In operating upon a patient with exophthalmos, therefore, extreme care should be exercised in the protection of the eyes.

The subject of iodine in hyperthyroidism was next discussed. The administration of iodine leads to remarkable changes in the hyperplastic thyroid. The colloid is increased, the iodine content of the dried gland is increased, and the epithelium is changed from the typical columnar type of the hyperplastic gland to a low cuboidal. Marine believes that the iodine causes an accumulation of colloid within the follicles and this through the agency of increased pressure causes a regression of the hyperplasia. Patients become refractory to the influence of iodine after this drug has been administered for about two months. For this reason physicians should not administer iodine to patients with hyperthyroidism if operation is planned for the near future. The administration of iodine should be left in charge of the surgeon.

Dr. Lahey discussed the group of patients which he has termed thyrocardiac. These are patients with hyperthyroidism and either auricular fibrillation or cardiac decompensation. The condition results from the overloading of a previously damaged heart by overactivity of the thyroid. The mortality from operations on thyrocardiacs has been about 4.25 per cent. About 97 per cent of patients have been permanently relieved of decompensation. Follow-up has shown, however, that the blood pressure continues to have a rising tendency in spite of operation.

The speaker next described the condition of intrathoracic goiter and illustrated the clinical picture and x-ray findings by lantern slides. About eight per cent of over 12,000 goiters at the Lahey Clinic have been intrathoracic. Symptoms of dyspnea and choking are prominent in this condition and most apt to come on at night when the bronchi are not kept so well cleared as during the daytime. The mortality from operation in this type of goiter has been only two per cent.

Dr. Lahey ended his talk with a consideration of tumors of the thyroid in which he brought out interesting points both in diagnosis and treatment. About 96 per cent of thyroid carcinomata arise from fetal adenomata. Metastasis of the histologically benign adenoma was explained by the fact that these tumors grow into veins and so are transported elsewhere in the body. The location and typical appearance of lateral aberrant thyroids were discussed and their relation to malignancy was emphasized.

An excellent discussion of the subjects presented was given by Dr. Allan Winter Rowe. He pointed out the numerous factors which influence the basal metabolic rate so as to make the determination unreliable. The blood cholesterol level may well be a better index of thyroid deficiency. Even this, however, may be hardly more than a rough index. Dr. Rowe said that the true significance of blood constit-

nents will be realized only when the laboratory sciences have progressed to such a degree as to enable us to interpret the various elements in terms of each other. Drs. Huxthal and Lahey answered several questions which had been asked during the course of the discussion.

NEW ENGLAND MEDICAL SOCIETY

The semi-annual meeting of the New England Medical Society will be held in the Evans Auditorium of the Massachusetts Memorial Hospitals, 80 East Concord St., Boston, on Thursday, May 31, at 8:15 P.M. The speaker of the evening will be Dr. Edward W. Archibald of Montreal, Professor of Surgery, McGill University Faculty of Medicine. His subject will be "The Aetiology and Treatment of Recurring Subacute Pancreatitis" (with lantern slides). Discussion by Drs. Charles T. Howard, Daniel F. Jones, Richard H. Miller, William R. Morrison and Lester R. Whitaker. All physicians interested in this subject are invited to attend this meeting.

AMERICAN PROCTOLOGIC SOCIETY

CLEVELAND MONDAY AND TUESDAY, JUNE 11-12, 1934

Headquarters: Hotel Cleveland.

Arrangements: T. E. Jones, Cleveland, C. C. Meckling, Pittsburgh.

Regular and orthodox practitioners, members of the American Medical Association, and not affili-

ated with medical groups admitting those not members of the A. M. A., are hereby cordially invited to attend the 35th Annual Meeting in Cleveland, Monday and Tuesday, June 11 and 12—the week of the A. M. A. meeting

For additional information, address the Secretary, Frank G. Runyeon, M.D., F.A.C.S., 1361 Perkiomen Avenue, Reading, Pa.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

May 25, 27, 28, and 29—The American Association on Mental Deficiency. Details may be obtained from the Secretary, Dr. Groves B. Smith, Godfrey, Illinois

May 28—June 1—American Psychiatric Association will be held at the Hotel Waldorf-Astoria, New York City

May 31—New England Medical Society. See page 1141

May 31—June 2—American Association for Thoracic Surgery. See page 1141

June 4—Worcester City Hospital Clinics. See page 1137

June 4—St. Vincent Hospital (Worcester) Clinics. See page 1137

June 5—Alumni Luncheon, Massachusetts Alumni of the University of Maryland Medical School. See page 1141

June 7—Faulkner Hospital Clinical Meeting will be held at 5 P.M.

June 7, 8, 9—Annual Meeting of the American Association for the Study of Gout will be held in Cleveland, Ohio. For details of the program apply to Dr. J. R. Yung, Terre Haute, Ind.

June 11—American Medical Golfing Association will meet at the Mayfield Country Club in Cleveland. For details see page 1090, issue of May 17.

June 11–12—The American Proctologic Society. See page 1141.

June 12—American Heart Association will meet at 9:30 A.M. at the Cleveland Hotel, Cleveland, Ohio.

July 24–31—The IVth International Congress of Radiology will be held in Zurich under the presidency of Professor H. R. Schnitz, General Secretary Dr. H. E. Walther, Gloriastrasse 14, Zurich.

August 18–September 30—Medical Study Trip to Hungary. See page 975, issue of May 10.

September 3–6—American Public Health Association at Pasadena, California. Dr. J. D. Dunshee, Chairman, Local Committee on Arrangements.

September 4, 5, 6—International Union Against Tuberculosis. For information address the National Tuberculosis Association, 450 Seventh Avenue, New York City.

BOOK REVIEWS

Teaching Methods in Medicine. By William D. Reid. 111 pp. The Graphic Press. \$1.00.

The purpose of this little book is to stimulate teachers in medical schools to find out whether there are methods of teaching developed in non-medical fields that might prove useful in medicine. The subtitle indicates that it proposes to discuss the application of philosophy of contemporary education to medical schools. The author foregoes inquiry into what the philosophy (if any) may be and dwells rather on certain facts about some types of contemporary education. Some "philosophies" of contemporary education have been developed as the result of attempts to educate sub-normal persons (the Montessori system, which perhaps is already mediaeval) or from efforts to educate groups of persons whose formal education closes with the junior high school because they have no intellectual interest in advance. This may be useful in analysis as the cinema film, run slowly or halted, shows elements in physical motion that escape the unaided eye. Yet to what extent these "philosophies" apply to university education is not made clear.

The background of the book is one of the most devastating criticisms possible of the present situation in medical education as it takes for granted that students of university grade need to have interest in their studies stimulated. "It is the teacher's job to see to it that the student experiences the 'will to learn, or feels a need for the learning' (p. 25). By what right are these persons studying medicine if they are not interested in their studies? It is to be

hoped that the rather dismal picture of medical education is not true of all medical schools

Nevertheless stimulating ideas often come from fields lying outside of one's formal major interest and there is need that teachers of medicine should become conscious of developments in the field of pedagogy. For the inexperienced teacher this is especially helpful, and there are in Dr Reid's book many useful hints, suggestions and directions. These are overlaid perhaps a little too much with the patter of the educationalists, and form a compilation of maxims rather than an integration of ideas about education. The book notes types of experiments among which the inexperienced teacher may find something suited to his immediate need. It does not supply a philosophy of education in the light of which procedures may be judged.

But the author claims in his preface that his book is only "suggestions." Accepting this statement rather than the more ambitious title as a criterion by which to judge accomplishment, the book may serve as a finger post to direct teachers of medicine to investigations of educational procedure so that they may find for themselves something by which they may become better teachers. The secret of excellent teaching is to have an excellent teacher. This fundamental consideration in education the book does not discuss.

Social Psychology By Abraham Myerson 640 pp
New York Prentice Hall, Inc \$3.50

This comprehensive volume includes all the various aspects of social psychology both from the descriptive and dynamic viewpoints. The fact that it is written by a physician and a trained psychiatrist of long experience and keen insight makes the volume of more practical value than similar treatises by non-medical psychologists who tend to delimit and isolate the various determinants of group psychology. Dr Myerson has been able to integrate and evaluate the neurological basis of human behavior, because of his opportunities to observe and study the effects of the visceral-organic structure upon the total personality.

The approach to the various aspects of social psychology is based upon two main theses, namely, that the visceral-organic structure of man is basic for an understanding of psychology and secondly, that apart from his group, man is a mere potentiality, it being necessary for him to develop in an environment which may foster, modify or even destroy his capacities. The student will find in this volume all the general material for the orientation of his studies with the more specialized fields of the social sciences particularly in the various discussions and detailed bibliographical references.

The book is divided into four parts: general social psychology, visceral social psychology, social psychology of the family and the social aspects of crime. It is emphasized that even individual psychology is social psychology, because the group is

an integrated whole and not a broken mosaic of isolated units.

Within the limits of a review, it is possible to indicate only briefly the rich material so well assembled and analyzed in this volume. It is refreshing to see the reflex as a unit of behavior, criticized, as such objective-experimental methods are inadequate to explain the complexities of human or even animal mental processes. One of the most interesting sections is that devoted to crime, particularly the description of that criminal type of minor delinquents which the author terms "unorganized extroverts," that is, individuals whose activities do not follow an organized or integrated plan. Sexuality and the digestive processes, as the two most important emotional drives, are visceral social affairs and are given an extended discussion because both enter psychologically and physiologically into human conduct, influencing mood, emotional satisfaction and even symbolization and morality. In fact, in the reproductive processes, one is not dealing with a sexual instinct but with a psycho-sexual one. Even character traits show this linking of mental and physical from gastro-intestinal activities, as shown by the reconstruction of the oral and anal character as formulated by psychoanalysis. The social structure continually modifies, inhibits and excites what is termed the 'curiosity mechanism.' It does this by means of diversified receptors which organize all individual experience. This learning-teaching mechanism is synonymous not only with intelligence, but extends to every visceral function, developing social attitudes and the dominance of the reality principle.

The volume can be highly recommended, not only for its lucid analyses and keen insight but also because the various approaches as developed by the author are so stimulating and provocative, that the reader will feel strongly inclined to pursue the various avenues of the subject.

Treatment in General Practice By Harry Beckman
Second Edition 889 pp Philadelphia W B
Saunders Company Cloth, \$10.00 net

The reviewer of this volume must confess to a previous bias against textbooks devoted especially to such subjects as prognosis, therapeutics, treatment, etc. Perusal of Professor Beckman's unusual work does much to dispel this bias. In well-written, often sparkling English the results are presented of a pharmacologist's investigations into the literature relating to the modern techniques of therapy. It is quite true as the author states in his preface that the subject of therapy is inadequately taught and that general rather than specific principles are emphasized. So much the more important is it therefore for the practitioner to possess a volume of this sort, in which the last word on the treatment of a given disease is presented in detail. To be sure this material may be obtained from the original articles, but these are scattered in so many journals that

their accessibility frequently becomes difficult or impossible to the average man Beckman reads all the articles, classifies them, examines them critically, and finally presents them to the practicing physician ready for immediate service in the case at hand A possible criticism is that multiple methods of treatment are frequently presented without an outline of what the author considers is the best program of therapy This may be valuable to the initiated but must be rather difficult to the novice

The book is startlingly up-to-date witness the inclusion of a section regarding the possible dangers of amidopyrine and related drugs in agranulocytosis, a recital of the doses of the various preparations of liver for parenteral use, etc The author's digestion of so many articles on so many diverse subjects does not appear to have influenced his critical faculties for his observations remain throughout quite sane The most valuable feature of the book is its exact detailed description of the methodology of treatment, often given in the direct words of the authorities quoted A section on "vehicles and incompatibilities," an alphabetically arranged bibliography of about 2500 references and an excellent index complete the volume

The Technique of Local Anesthesia By Arthur E Hertzler Fifth Edition 292 pp St Louis C V Mosby Company \$7.50

Hertzler aims to present briefly and simply his own technique of local infiltration anesthesia and to lay very little emphasis on the methods of regional anesthesia. He appears to draw from profitable and very extensive personal experience By mingling descriptions of surgical methods with local anesthesia technique, he points out how operations may be adapted to the demands peculiar to local anesthesia He has a sane realization of the limitations of local blocking, and with each region of the body discusses without prejudice the relative merits of that method and of general anesthesia This is one of the most distinctive and valuable characteristics of the book

Although he stresses the importance of accuracy of technique and the use of small amounts of a solution, yet unfortunately in the detailed directions he too frequently omits mention of the amounts to be used He discards nupercaln from consideration quite properly, but defends the use of quinine and urea hydrochloride His unreserved recommendation of diothane, a new drug of questionable merit, appears ill-advised There is no mention of the prophylactic use of the barbiturates, nor of the treatment of procaine toxicity

The illustrations are of good quality and number but unfortunately some of them are not labeled Detailed instructions are clear and adequate on many subjects, notably inguinal and umbilical hernias the bladder the male and female genitalia the rectum, the branches of the fifth cranial nerve, and the paravertebral injection of the thoracic nerves The general discussion concerning abdominal anesthesia is excellent. It includes the indica-

tions for local anesthesia, the neurological anatomy involved, and the sensitiveness of the viscera to various types of stimulation under varying degrees of inflammation. He agrees with others in placing little dependence on splanchnic anesthesia It is disappointing to find that he has nothing to offer in the way of local infiltration anesthesia within the abdomen

Many descriptions of technique are not clear, or seem very inadequate These include local anesthesia of the upper jaw antrum for glands of the neck, for the tongue, the breast and for fractures of the extremities, also sacral nerve block, and regional methods for the hand and forearm For example, the reader is told 'If the interior of the nose is to be entered the nerves supplying this region must be blocked The local use of anesthetics within the nose does not give good results He is then left to search for other sections of the text which will describe the nerve supply concerned and the methods of blocking it

The chapter on spinal anesthesia written by Arch E Spelman M.D. covers the practical aspects of this subject very clearly and well It deals with the use of procaine only

Because of the inadequacy of detail of most of the descriptions of technique, this book seems ill-suited to the surgeon or anesthetist who wishes either a systematic course of instruction or a handbook for quick reference It would, however, serve as a moderately helpful adjunct to the definitely superior texts available on regional anesthesia

Laboratory Medicine A Guide for Students and Practitioners By Daniel Nicholson Second Edition 566 pp Philadelphia Lea & Febiger \$6.50

The first edition of this work appeared in 1930 and was reviewed in these columns The present edition is a larger, heavier, and slightly more expensive volume Many of the interpretations have been expanded and the following procedures have been added the cough plate for diagnosis of whooping cough, pneumococcus typing by the rapid capsular reaction Corper's simple method for culturing the tubercle bacillus in sputum quantitative agglutination tests for the typhoid paratyphoid group also for undulant fever and tularemia, intradermal tests for echinococcus infection, the patch test in eczema, pregnancy test by Friedman's rabbit method, examination of synovial fluid, urea clearance test for renal function Congo-red test for amyloid disease by drogen ion concentration of urine urinary diastase blood cholesterol reaction, methemoglobin and sulfhemoglobin reactions, the histamine test to evaluate circulation of the lower extremities and the use of the ultrapak microscope in rapid tissue diagnosis

The illustrations have been increased from one hundred and eight to one hundred and twenty four and are as well reproduced as they were in the first edition For those who wish an excellent reference volume on laboratory medicine Dr Nicholson's book fulfills all requirements

NEW ENGLAND SURGICAL SOCIETY

THE DIAGNOSIS AND TREATMENT OF SUBDURAL HEMATOMATA*

A Report of Sixty-two Cases

BY DONALD MUNRO, M.D.†

IN a paper written thirty-one years ago on subdural hematomata under the name of Pachymeningitis Haemorrhagica my father¹ stated that the interest up to that time (in this disease) had been almost exclusively pathological and that he wished to emphasize that it should be more frequently surgical. I believe that in essence this statement is as true today as it was then. Because of our present failure to recognize the acute stages of so-called chronic subdural hematoma except at postmortem we fail to identify the latter as a late stage of the former and neglect the majority in favor of the minority. Thus, paper presents my evidence in support of these statements and summarizes data obtained from a study of 62 subdural hemorrhages admitted to the Boston City Hospital during four and one-half years. Both "acute" and "chronic" forms are included. Forty-one were on the Neurosurgical Service under my care. Of the remaining 21, 10 occurred on the medical services and the rest (11) on the general surgical side.

LITERATURE. A survey of the literature for the past 10 years demonstrates that the clinical or surgical side of this problem has been largely investigated through information derived only from the study of small groups of cases. Seventy-three articles published during this period have been available for review. Of these thirty-seven were single case reports. In fifty-four the authors' experience was limited to no more than five and in sixty-six to no more than 10 cases. Five offered no more proof than the author's opinion that he was dealing with the disease in question. Of the remaining two, one by Jelsma¹⁶ is a compilation of forty-two cases selected from the literature to which he has added two of his own. The other records Coleman's¹² personal experience with twenty instances and includes both the "acute" and "chronic" forms of the disease. Though not given in such detail I

From the Neurosurgical Service at the Boston City Hospital.

First read at the Annual Meeting of the New England Surgical Society, September 29, 1933, at Boston, and subsequently at a meeting of the New York Neurological Society, February 6, 1934, at New York.

*Munro, Donald—Visiting Surgeon, Neurological Surgery, Boston City Hospital. For record and address of author see This Week's Issue, page 1154.

should infer that his conclusions are fundamentally similar to mine and certainly from the surgical point of view are the only ones that merit serious attention from among this group.

Isolated observations of value when taken in conjunction with the whole mass of data were frequent however. For example it has thus been demonstrated that subdural hematoma may occur one hour, five, and a half and sixteen months postpartum^{17, 18, 5} that it may remain quiescent long enough to permit complete calcification even at the early age of eleven years^{19, 20} that it may be associated with syphilis²¹, scurvy⁵ or cerebral tumor^{22, 11}, that it is uncommon in congenital syphilis under two years of age²³ that children are not immune^{24, 25, 26, 5} and that it is a rare but possible occurrence in the posterior fossa²⁷. Encephalography and ventriculography have both been successfully used as diagnostic measures. Removal of the clot has been successfully carried out through trephine holes¹⁴, by bone flaps¹² and by means of multiple operations²⁸, and finally a therapeutic bone defect in the skull has been closed by a platinum plate²⁹ in the course of the treatment of this disease.

INCIDENCE. Autopsy statistics from Chicago by Le Count and Apfelbach² and from New York by Vance³ list subdural hematomata as among the commoner complications of cranio-cerebral injuries (Chart I). The former found 300 among 374 fractures of the skull and the latter recognized it as the cause of death in 132 out of 512 autopsies or twenty-five per cent. At the Boston City Hospital for a period of four years up to 1933 it has been noted thirty-six times among 1352 head injuries. This is at the rate of 2.6 per cent. These cases were all on the general surgical or medical services. With one exception the diagnoses were either not confirmed or were made at autopsy. Conversely in the past twelve months from January 1933 on the Neurosurgical Service at the same institution thirty-five of the thirty-seven proved subdural hemorrhages among 201 head injuries were diagnosed clinically. This is at the rate of 17 per cent. It is obvious that previous to 1933 at the Boston City Hospital many such cases were not

only been undiagnosed but their presence has not even been suspected. Once the frequency of this condition had been appreciated and diagnostic methods improved to a point where early treatment could be instituted, many more cases were recognized. The resultant drop in mortality among verified cases from 100 per cent on the general services to 41 per cent on the Neurosurgical Service has been striking.

fluid Naffziger⁶ directed attention to this condition in 1924 and more recently (1932) Peet and Kahn⁷ described it in infants. It was noted seven times among my cases.

PATHOLOGY A detailed study of the histopathology of the subdural hematomata removed at operation, particularly in regard to their microscopic structure and its relationship to the

Vance's figures	512	132	25.0%	—	—	132

ETIOLOGY Trauma is generally recognized as the chief and by some authors as the only cause of this condition. Henschen⁴ however points out that there may be other causes, mentioning among other things, disease of the blood and blood-forming structures, arteriosclerotic changes, syphilis and even experimental avitaminosis (Chart II). Nutritional diseases in

time elapsed between their formation and removal must be reserved for later presentation. Suffice it to say that certainly within three hours after receipt of the injury and the presumed formation of the clot, a single layer of fibroblastic cells has already extended from the dura well onto the surface of the former. The process that eventually is to terminate by encapsulation

children are also a frequent cause⁵. Four of my cases were complicated in this way, three by syphilis and one by the presence of hemophilia.

The source of the hemorrhage in the "chronic" form is stated to be for the most part either from a rupture of a bridging cortical vein or of a tributary to one of the large venous sinuses. Although not necessarily so, it is probable that this is true of most of the cases in whom symptoms develop slowly. Taken in relation to the whole group, however, this is only a small number. Both Le Count² and Vance³ find these to be unusual or rare origins for subdural hemorrhage in autopsied cases. My figures are in agreement with theirs in that fractures of the skull, and laceration and contusion of the brain are much more frequently the causative agents of the bleeding than the rupture of a single vein. The hemorrhage may also be so small as to escape notice even after the subdural space is open. In such cases the symptoms are caused by an associated collection of

of the free blood with organization of that portion adjacent to the capsule plus associated liquefaction of the more distant central parts has begun.

There is abundant indirect clinical evidence, based upon the frequent occurrence of a "latent period" in the development of symptoms, that such clots may slowly increase in size. The favorite explanation of this phenomenon has been to predicate repeated or slow seeping hemorrhages. These occur inside the clot from thin-walled blood spaces or "giant capillaries" and may produce multiple neo-membranes¹⁰. Such a condition is usually fatal however and is not a necessary prerequisite for a latent period. An equally reasonable explanation of this phenomenon has been offered recently by Gardner¹¹ and also during the past year, although apparently independently by Fischer and de Morsier¹². The former has shown experimentally that a given subdural clot which presents only a mini-

imum of signs at the time of its original formation will, after partial liquefaction, absorb by dialysis from the subarachnoid space sufficient fluid to enlarge it from 39 to 103 per cent. This flow results from the proximity of a highly concentrated protein solution to another solution in which the protein concentration is very much lower, the sole means of separating the two being the arachnoid which acts as a dialyzing membrane. I have been able to show that this experimental relationship holds true also in the human being. My figures when plotted graphically (graph 1) further suggest that there is a

ation and analyzed for me in F. Fremont-Smith's laboratory I have found that during the first twenty-four hours after injury the protein content averages 1100 mg per cent, the low being 500 and the high 1700. An average peak of 10,200 mg per cent is reached between the fifteenth and twenty-first days. The highest concentration occurred on the twenty-first day and was 12,168 mg per cent which is almost double that found in blood serum. Thereafter the fall is rapid to the twenty-seventh day, the average content at this time being 2200 mg per cent. From this point to the ninetyeth

period during which the protein concentration of the fluid part of the clot increases. This is due in part to liquefaction of the clot. In addition the protein subsequently breaks down into smaller molecules*. Both these factors produce a rising osmotic pressure within the solution. A peak is then reached and thereafter there is a steady dilution with resultant lowering of the concentration, although at no time up to five and a half years does the subdural protein ever descend to the level of that in the subarachnoid space. This dilution proceeds rapidly by osmosis until blood serum concentration levels are reached. After that the process is slowed up, the rate depending on the proximity of the fluid to a capillary bed with resultant provision for the diffusion therefrom of the end products of the protein destruction. Based on a study of 25 fluids removed at oper-

ation and analyzed for me in F. Fremont-Smith's laboratory I have found that during the first twenty-four hours after injury the protein content averages 1100 mg per cent, the low being 500 and the high 1700. An average peak of 10,200 mg per cent is reached between the fifteenth and twenty-first days. The highest concentration occurred on the twenty-first day and was 12,168 mg per cent which is almost double that found in blood serum. Thereafter the fall is rapid to the twenty-seventh day, the average content at this time being 2200 mg per cent. From this point to the ninetyeth

day the fall is much slower with a shrinkage of only 700 mg per cent. Even at five and a half years the protein concentration in one case was still 140 mg per cent. On these figures, which are admittedly too few to be finally conclusive in detail, it seems to me fair to assume that there is a liquefaction and breakdown of the clot extending from the first to between the fifteenth and twenty-first days. This solution then becomes more and more diluted, rapidly for the first ten days and progressively more slowly thereafter, without ever actually reaching the low concentration level of the cerebrospinal fluid even after five and a half years. The corollary to this process of dilution is necessarily an increase in the amount of the diluted fluid and therefore an increase in the size of the hematoma. This is expressed clinically in terms of symptoms of an expanding lesion and occurs without necessarily any further addition in the form of secondary or late hemorrhages. Blood in the cerebrospinal fluid (graph 2) as found at lumbar puncture does not essentially

In one case simultaneous determination on the subdural fluid and blood serum on the day of operation gave the following comparative figures—serum protein 2200 serum $\text{N} \text{ P} \sim 28$ serum chloride 601 subdural protein 6300 subdural $\text{N} \text{ P} \sim 33$ subdural chloride 605. Such figures can only be accounted for by the breakdown of protein within the subdural fluid.

alter the shape of the graph though the findings are less convincing because the cases are fewer in number. This is likewise true (graph 3) when the cases in whom a clot was proved to be present are segregated from all others and that the graph may be false and with added experience may well conform to the shape of the others. Such as it is however, this graph has an initial rise that is so abrupt as to be almost perpendicular. In addition the level of

plotted. Even the high point of the peak is approximately at the same level in all curves.

When the cases in whom at operation a subdural clot was grossly absent are considered, however, there is an interesting variation. To be sure this is only a tentative suggestion because the number of cases involved is so few

the peak is some 4000 mg per cent lower than the others while the low level of slow dilution is reached much earlier. The protein concentration is much less at the start (200 as compared to 1200 mg per cent), the peak is reached between the fifth and tenth days instead of the fifteenth to twenty-first and the abrupt part of

the dilution curve reaches its point of leveling off at the twenty-first instead of the forty-seventh day. These cases are similar to those heretofore known as "hydrops of the subdural space." My feeling pending further data is that they rather represent a condition in which the subdural space has been filled with a very small amount of hemorrhage and a relatively large amount of cerebrospinal fluid which for want of better explanation we may presume has come there through a tear in the arachnoid membrane. A minimum amount of this blood has clotted but the rest has remained at first mixed with and then in solution, in the cerebrospinal fluid. Such reasoning is supported by the abrupt rise in the first part of the graph and the lower level of the protein value at the peak. Dilution then proceeds more rapidly because there is no further solution taking place as illustrated by the steeper slope and earlier low point of the second part of the curve. Such cases should have as a class a minimum latent period and if any of the symptoms of increasing intracranial pressure develop they should be relatively mild in character.

From a consideration of the above clinical and chemical evidence, particularly when viewed in the light of Gardner's experimental work I believe that we may reasonably look upon subdural hematomata as potentially expanding le-

sions. The length of the latent period will be related to the amount of cerebrospinal fluid mixed with the blood at the time of the injury, the rapidity of the liquefaction and molecular breakdown of the solid clot, the thickness and nutrition of the organized capsule of the hematoma which surrounds the central liquefied area and the approximation of the latter to a capillary bed. These relationships will be in an inverse ratio, i.e., the greater the amount of cerebrospinal fluid admixture the shorter the latent period, etc. Furthermore under such conditions it is probable that a certain number of hematomata in which the process of repair rapidly outdistances the process of destruction will remain almost completely solid for long periods, even months or years. On this basis it is evident that the pathological picture of chronic subdural hematoma is but a late variant of the acute phase and that at the late stage the hematoma may be liquid or solid or both depending upon the osmotic relationships that have been formed.

DIAGNOSIS In my experience the diagnosis of subdural hemorrhage can be made only by exploration. I believe that this procedure is always indicated in those cases in whom adequate treatment for one of the commoner craniocerebral injuries fails to bring about improvement (Chart III). To be sure it is inevitable that in

any such exploratory procedure there will be a certain number of unnecessary operations. In this type of case, however, I believe that a properly conceived procedure carried out in an adequately equipped clinic after the patient is out of surgical shock alters little if at all his chances of recovery should it prove to have been unnecessary. On the contrary if a hitherto unrecognized clot is found, his chances are immeasurably improved. The procedure should consist of a trephination of both squamous temporal bones under local anesthesia with sufficient enlargement of the bony opening to permit of subdural exploration with a brain spoon in all directions. During 1933 such a procedure has been carried out in my clinic fifty-one times. In twelve of these no sub- or extra-dural blood was found. Of these twelve, eight were suffering from a lacerated brain or intracortical hemorrhage of such nature that operative interference could accomplish nothing, but no case so far as could be told succumbed because of the operation.

Subjective Symptomatology Historical data as compiled from the records of these patients with subdural blood are interesting and suggestive but of little selective diagnostic value.

only fifteen times in this series. The shortest of these was two hours which occurred twice and the longest two and a half years. The other times were one day three times, two days twice and three, five, six, seven, forty-two, fifty-two and eighty-four days. To be sure there were other cases in whom it was impossible to determine either the time of injury or the time of onset of symptoms, but even with these included the number is only twenty-three or approximately one third of the total. Convulsions have been conspicuous by their absence. Having in mind the location of the lesion this finding has been rather surprising.

We may conclude then, that patients suffering from a subdural hematoma will present a history of injury to the head followed in practically every case by some degree of unconsciousness and very often by headache. Their friends and family will subsequently note peculiar actions and speech which on analysis will be found to be due to abnormal mental activity. If the clot is not too large and the original injury is trivial, a latent period with mild or no symptoms may follow. This may be absent or may vary in length up to years but it need not therefore be concluded that more than the original hemor-

CHART IV
SYMPTOMATOLOGY—SUBJECTIVE

	History of Injury	Loss of Consciousness	Headache	Convulsions	Mental Change	Latent Interval
Positive	52	55	32	13	57	15
Absent	8	5	1	45	4	39
No note	2	2	29	4	1	8

(Chart IV) A history of injury was practically constant and where it occurred was severe in three-fourths of the cases. Loss of consciousness was even more common, occurring in association with each injury and in addition three times where no such history was obtainable. Headache was definitely absent only once, being definitely present in about half the cases. Its presence or absence was unascertainable in the rest of the cases because of unconsciousness. Such symptoms are common to almost all forms of brain injury however.

Mental changes other than unconsciousness and sufficiently obvious to be recognizable by family or friends were unexpectedly frequent. This appears to be one symptom whose presence definitely suggests subdural hemorrhage. A "latent interval", usually defined as the time that intervenes between the receipt of the injury and the onset of symptoms, has been commonly accepted as an essential finding in this condition. I believe the importance of its presence has been much overrated. This is undoubtedly due to the fact that the conception of the acute subdural hematoma as a clinical entity has been completely overshadowed by the intense study of its late form. Such a latent period occurred

rhage has occurred. These patients will only rarely have convulsions.

Objective Symptomatology (Chart V) This is no more selective than the subjective. However abnormalities are sufficiently common so that if physical and neurological examinations are carried out enough will be found to justify hospitalization immediately after the injury. The blood pressure was elevated 21 times. This was in each case due to the increased intracranial pressure and subsided again to normal levels after removal of the clot. However it was normal even more often, so that elevation is by no means essential in making the diagnosis. Some abnormality on physical examination pointing to an injury was found in 49 of these patients. Easily elicited signs of alterations within the nervous system were found fifty-eight times. Recognizable mental changes were most common (fifty-three) although signs of interference with the neuromuscular apparatus occurred almost as often (fifty). Paralysis in the cranial nerve fields was present thirty-six times. Twenty-six of these were in the facial distribution. This is evidence of the usual site of the clot. Abnormalities were recognized in the eyegrounds only ten times. An ipsilateral di-

lated pupil has been described by several authors⁹⁻¹⁰ as a reliable localizing sign in these cases. This is contrary to my experience. Twenty-five showed no dilatation at all, fourteen were dilated on the side opposite the hemorrhage, three were dilated bilaterally and fourteen on the ipsilateral side.

We may conclude then from the examination of the patient that if his blood pressure is normal or elevated, his physical and neurological examinations abnormal, if he shows mental changes and has a paralysis of one facial nerve,

headache, mental changes, an abnormal physical and neurological examination, a paralysis of one facial nerve and a bloody cerebrospinal fluid under increased pressure and who can subsequently have a latent period free of symptoms, may have a subdural hemorrhage. If improvement of these signs and symptoms does not follow proper treatment by dehydration and lumbar puncture, this diagnosis should be confirmed or ruled out by a bilateral exploratory subtemporal trephine. It is equally true that if, in a patient known to have a lacerated brain,

CHART V

SYMPTOMATOLOGY—OBJECTIVE

Normal	10	2	6	5
Decreased	1	1	—	—
Not done			33	1
Not given	14			

Cerebrospinal Fluid (Chart VI) Examination of the cerebrospinal fluid will serve only to identify the presence of an increased intracranial pressure and blood from an associated contused or lacerated brain. A little more than half of these cases had a high intracranial pressure and a few less than half had evidence of subarachnoid bleeding. The protein content was increased only in the presence of fresh or old blood and never approached the levels found in the fluid collected from the subdural space.

On the basis of all the above findings I feel that a patient who has been knocked unconscious following a blow on the head, who has a

the neurological signs fail to clear up, unconsciousness deepens, delirium or mania develops, the pulse drops to below sixty and the cerebrospinal fluid gets less bloody even though the pressure may be either high or low, some additional and hitherto unrecognized condition must be present. If study of the fluid intake and output relationships and determination of the sugar and cellular content of the cerebrospinal fluid rules out toxic dehydration and meningitis, bilateral exploratory subtemporal trephine is the only remaining method of disproving the added presence of such a sub- or extra-dural hemorrhage.

TREATMENT It is unanimously agreed that once the diagnosis is made and the patient is no longer in a state of surgical shock, the treatment of subdural hematoma is exclusively surgical. Opinions regarding the best technical method to use are still divided, however. Coleman¹¹ who reports the next largest personal series advocates large decompressions in the acute, and osteoplastic flaps in the chronic types. Putnam¹² prefers an osteoplastic flap though recently he has discarded this for a decompression in acute cases. McKenzie¹³ has used the flap method in the past but has abandoned it in favor of small trephine holes with tube drainage. Fleming and Jones¹⁴ in eight cases used through and through irrigation between trephine holes placed front and back. There is also a great

variation in opinions relative to the value of complete as opposed to incomplete removal of the clot and membranes. On the other hand drainage, especially in association with decompression, is popular.

I believe that the most effective procedure is the one that is easiest and quickest and that still gives an adequate exposure. In addition if it can be made to, it should be so designed as to be of use during the postoperative period. These criteria are best fulfilled by the ordinary subtemporal decompression. This is true, however, only when the bony and dural opening is extended to the limits of the squamous portion of the temporal bone. This operation can be done easily and rapidly and is centered over the most common site of these lesions. The entire cerebral subdural space can be adequately explored and therefore the entire extent of the clot can be removed, preferably by suction. In addition the degree of tenseness of the scalp over the decompression opening will be of help in the early recognition of an increased intracranial pressure.

Drainage of the subdural space should be practised. This will be necessary, not on account of any secondary hemorrhage, but because it is impossible to completely remove all the abnormal content of the space at the time of the operation. It will not always prove efficient, however, because the tract may be completely closed within a few hours by the swollen cortex. A possible exception to this may be noted if a tube drain is used as recommended by McKenzie.

I believe that the entire clot should always be removed. One of the cases in this series died because this precaution was neglected. If exploration of one side fails to reveal any pathology the other side should be invariably opened regardless of any of the symptoms that have been present. In the presence of a complicating contusion or laceration of the cortex, irrigation with salt solution should be avoided. In two cases a local edema was produced in a previously normally pulsating brain in this way. It developed so rapidly that it interfered greatly with the closure and it was necessary to give hypertonic glucose solution intravenously while the wound was still open to prevent further splitting of the cortex. A very common but not constant complication is a severe edema of the cortex. This may be limited locally and not cause any general increase in intracranial pressure. In such cases lumbar puncture drainage is useless and the large decompression is a great help which I am sure enhances the effect of the dehydrating agents that must be used. If the edema is generalized and the intracranial pressure rises, the safety valve action that is provided is also distinctly useful in association with lumbar puncture drainage. A possible

cause of this edema is the overexpansion of the previously compressed brain in an effort to fill the abnormal space left after removal of the clot. In this connection Henschen⁴ advocates the intravenous administration of sterile water on completion of the operative procedure. This is an interesting suggestion and quite at variance with all others that have been made for solving this particular problem. I know of no one else who has had experience with it.

In my hands this postoperative edema has been best treated by 50 per cent glucose intravenously, 100 cc at a time. This dose may be repeated every two hours for five doses if necessary. Caffeine given in the same way is also useful if the respirations begin to fail. It is of no help when given by other methods. As a last resort 200 cc of a sterile 2 per cent solution of MgSO_4 can be given intravenously. This is heroic treatment and dangerous. It must be given slowly and, if efficient, will produce a toxic dehydration which of itself may be fatal. This is only of use if there is an adequate circulation. If hyperthermia develops, cracked ice enemas and warm sponges followed by the exposure of the entire body surface to a gentle steady breeze from an electric fan has accomplished a great deal.

This edema is a most alarming and serious complication. Its successful treatment requires constant attention on the part of the physician and the use of all possible and reasonable procedures. Reoperation is contraindicated however. It should be further noted that as the result of the therapy, a toxic dehydration may set in, which in its turn will require active interference. On this account an accurate daily chart of the fluid intake and output must be kept. Of the thirty-nine cases subjected to such operative and postoperative care as outlined above, sixteen died, a mortality of 41.2 per cent. This is of course high, but is not to be

CHART VII

MORTALITY

	Total Cases		Mortality Per centage
	Living	Dead	
Without operation	0	22	100%
With operation—Neurosurgical	23	16	41.2%

considered in comparison with the 100 per cent mortality that follows failure to recognize the frequency of this condition until it is discovered by the pathologist.

ILLUSTRATIVE CASE REPORTS

ETIOLOGIC AND PATHOLOGIC VARIATIONS

Rupture of Cortical Bridging Vein No. 23. A case of right temporoparietal subdural hematoma caused by rupture of bridging cortical vein following a

homicidal blow kindness of Dr Timothy Leary
This young adult white male was admitted to the hospital on a medical service Sept. 28, 1932 after having been discovered unconscious by the police ten minutes previously. The admission diagnosis was alcoholism. Subsequent investigation showed that he had been last seen the previous night and was normal in every way at that time. On admission he was in moderate shock with flushed face and an odor of alcohol on his breath. Temperature 98° pulse 90 and respirations 32. Physical and neurological examinations were negative except for abrasions and contusions of the forehead, the lips and mucous membrane of the mouth and the left upper and lower eyelids. Death ensued in a few hours. Autopsy showed a large right temporoparietal subdural hematoma caused by the rupture of a vein which ran from the surface of the temporal lobe to the adjoining dura. There was no fracture of the skull and no injury to the brain.

Lacerated Brain with Cerebral and Cerebellar Hematomata and Bloody Cerebrospinal Fluid No 58
A case of right cerebral subdural hematoma together with a cerebellar subdural hematoma caused by the tearing of cortical vessels in association with contusion and laceration of the brain operative removal of the cerebral hematoma. Death eleven days later with discovery of the cerebellar hematoma at autopsy. This thirty-eight year old white male who was said to be a "bleeder" was admitted on October 27, 1933 with the history of having gone on a "drinking party" nine days before. The following day he was stuporous and restless. Lumbar puncture showed bloody cerebrospinal fluid under a pressure of 280 mm water. With repeated punctures for the succeeding six days he at first improved and then gradually lapsed into coma again. On admission his temperature was 101.4° pulse 84 respirations 25 and blood pressure 132/102. There was a dilated right pupil, a spastic left arm and a weakness of the entire right side. There was a bilateral ankle clonus and dorsiflexion of both great toes. A right subtemporal decompression was made and through it a liquefied subdural clot completely surrounded by membrane and covering practically the entire right cerebrum was removed. The fluid portion showed 7724 mg per cent of protein and the membrane was that of a subdural hematoma with well organized new membrane formation. The patient improved for twenty-four hours and then lapsed back into coma. The intracranial pressure rose to and remained around 250 in spite of seven lumbar punctures. As a result on Nov. 1, 1933 an exploratory left temporal trephine was made. The brain was flattened and did not pulsate but was otherwise normal. Puncture of the lateral ventricle showed clear fluid under abnormally high pressure. The removal of which was followed by pulsation of the brain. Unconsciousness continued however to be followed by bouts of hyperthermia and a left sided convulsion four days later. Two days later hypostatic pneumonia and death ensued. Autopsy showed a bilateral cerebellar subdural hematoma.

Cerebral Subdural Hematoma with Clear Cerebrospinal Fluid an Ipsilateral Hemiparesis and Epilepsy No 16
A case of left fronto-parieto-temporal subdural hematoma caused by bleeding from an unidentified source following an injury sustained during an epileptic seizure. Bilateral subtemporal exploration with left decompression and removal of a fronto-parieto-temporal subdural hematoma. This twenty-seven year old white single male who was known to have had generalized epileptic convulsions for at least ten years was admitted for the third time in three years on September 12, 1933. The epilepsy has remained stationary for three years except for a

moderate slowly progressive mental deterioration. Twenty-six days before admission he fell striking his head. A rather constant occipital headache, nausea and vomiting and increasing drowsiness followed. Examination revealed a vertical nystagmus, a left hemiparesis including the face, a tendency to hold the right arm in a catatonic posture and a dry skin and tongue. There were no abnormal reflexes but there was a slight irregularity of the left pupil. Lumbar puncture showed clear fluid with no cells under a pressure of 140 mm water. On September 12, a right-sided subtemporal exploratory trephine revealed a normal brain under increased pressure with marked edema and flattening. A left-sided subtemporal decompression disclosed a clot over the anterior two thirds of the hemisphere lying in the subdural space and solid except for a liquefied area in the centre. This was removed including the membranes. The patient made an uninterrupted recovery and was discharged on Sept. 25, 1933, 13 days after admission. Microscopic examination of the membrane showed a well-organized subdural hematoma and chemical examination of the fluid part of the clot yielded a protein of 5340 mg per cent.

A Combination of Cerebral Subdural Fluid on the Right and a Cerebral Subdural Hematoma on the Left with clear colorless Cerebrospinal Fluid No 8
A case of right sided cerebral subdural fluid without clot in combination with a left sided cerebral subdural hematoma following an injury sustained playing football. Drainage of the right subdural space with decompression, attempted ventriculogram which was followed twenty-five days later by removal of a right frontotemporal subdural hematoma and a right sided decompression. Recovery with permanently increased intracranial pressure. This eleven year old white boy was referred by Dr. Chute of Osterville and admitted on December 8, 1932. He was injured during a football game on November 17, 1932 but was never unconscious. During the following week he developed a headache though he continued at school. Subsequently his headache grew worse he vomited, became semiconscious and was disoriented. The physical and neurological examinations were negative except for his mental state, an early choking of the discs, a weakness of the left external rectus muscles and a right pupil that was larger than the left. Lumbar puncture yielded clear fluid under a pressure of 300 mm water with protein of 27 mg per cent and a sugar of 87. On January 1, 1933 a right subtemporal decompression was made and a large amount of clear yellow fluid removed from the subdural space. The brain was compressed and the arachnoid firmly plastered against the pia. No clot was visible anywhere. The fluid was neither measured nor examined. Following this procedure he was symptomatically better but continued to run an intracranial pressure of about 250 mm water in spite of almost daily lumbar punctures. On January 20, ventriculogram was attempted but the films were unsatisfactory. Lumbar punctures were continued with out further improvement until February 14, 1933. On this date a left subtemporal decompression was made and through this a thick walled cyst covering the temporal lobe was emptied of one and one fourth ounces of thick serum like fluid. The collapsed cyst wall which was unquestionably that of an old organized hematoma was then removed. Microscopically the cyst wall was that of a well-organized subdural hematoma. The fluid contained 666 mg per cent of protein. Following this the patient's symptoms and signs completely cleared up except for a persistent elevation of intracranial pressure to about 250 mm water. In spite of this he was discharged symptom free on March 5, 1933.

Cerebral Subdural Fluid with a Lacerated Brain

and Bloody Cerebrospinal Fluid but no Hematoma No 37 *A case with a collection of brownish yellow subdural fluid over the left cerebral hemisphere associated with a laceration of the brain following an automobile accident Bilateral exploratory trephine with left decompression and drainage of the left subdural space Recovery* This thirty five year old white male was admitted to a general surgical service on April 12, 1933 following an automobile accident. He was unconscious and remained so for two days. There was a compound fracture of the left frontal region, bloody cerebrospinal fluid under a pressure of 450 mm water, a left facial paralysis and a pulse between 50 and 60. He was irrational, delirious, restless and apparently aphasic. On April 18 he was transferred to the neurosurgical service on account of deepening coma and failure to improve under dehydration and repeated lumbar punctures. After a period of observation and treatment to rule out the possibility of toxic dehydration a left exploratory subtemporal trephine was made and enlarged to a decompression. Through this opening a large quantity of thick yellow brown fluid escaped from the subdural space. This fluid contained 4300 mg per cent of protein. After its removal it was possible to survey the lateral surface of the entire hemisphere. This was stained a deep chrome yellow. The subarachnoid space which at first was completely empty gradually refilled, and a small laceration of the surface of the temporal lobe was discovered, but nowhere could either a hematoma or the membranes of a liquefied hematoma be found. A similarly placed exploratory trephine was made on the right side but the brain and its membranes were normal. His signs and symptoms completely cleared up and he was discharged relieved May 8, 1933, 24 days after admission.

Cerebral Subdural Hematoma with a Protein Content of the Liquefied Clot almost Double that of Normal Blood Serum No 49 *A case of right cerebral subdural hematoma from an unknown source which developed following a recent drinking bout in a chronic alcoholic who also had cardiovascular syphilis. A bilateral subtemporal decompression with evacuation of a partially liquefied subdural hematoma was followed by relief of symptoms and discharge eleven days after operation.* This fifty two year old white male was admitted to a medical service on October 19, 1933 because of vomiting and stupor. He had previously been admitted to the alcoholic ward several times. He stated that he had been drinking continuously for five days and that for three days he had been feeling depressed, and had had a pain in the back of his head. This pain followed a fall down two steps which occurred three weeks previously. He presented a right sided weakness bilateral Babinski's thick mumbling speech incontinence and irregular but equal pupils. He had a blood pressure of 172/102 with an enlarged heart with a systolic murmur at the apex, aortic area and neck. His blood Kahn was positive. On October 20, 1933 he was transferred to the Neurosurgical Service and on October 21, 1933 bilateral subtemporal decompressions were made, the brain on the left being flattened and edematous. On the right there was a partially liquefied "currant jelly" subdural hematoma covering the entire lateral aspect of the hemisphere. No laceration or other source of the hemorrhage was found. Following this operation and a period during which he was in surgical shock his symptoms and signs cleared up. His intracranial pressure which before operation was 350 mm water with clear fluid fell to 170 mm water and he was discharged relieved on November 1, 1933 ten days after operation.

UNUSUAL SUBJECTIVE SYMPTOMATOLOGY

A Fatal Case of Extensive Acute Cerebral Subdural Hematoma with no History of Injury No 44. *A case of large left cerebral subdural hematoma following one hour after swimming and the ingestion of a heavy meal, and associated with acute vascular hypertension. Operative removal through a left subtemporal decompression followed by rapidly advancing postoperative cerebral edema, circulatory failure and death.* This fifty nine year old white male was admitted to a medical service on August 2, 1933 with a history of headaches for three to four years from an undetermined cause and with a known systolic blood pressure for the past year of only 135. Ten days before admission, after swimming and a heavy meal, he had a severe headache and fainted. It was categorically stated that he had had no fall or other injury at any recent time, nor before, during or after swimming. On examination he was stuporous with a blood pressure of 220/110, a dilated left pupil, early choking of the discs, a bilateral Babinski and a left sided weakness including the tongue and face. Lumbar puncture showed a xanthochromic fluid with eight lymphocytes and no red blood cells, under a pressure of 250 mm water. He was transferred to the Neurosurgical Service the following day and operated upon at once. A left subtemporal decompression was made and a "currant jelly" subdural clot which covered the entire lateral surface of the hemisphere was removed. This was thickest and most adherent over the occipital cortex but no source for the bleeding could be found. One hour after operation his temperature rose to 102 and his pulse dropped to 60. The blood pressure was only 70/40. A lumbar puncture showed a cerebrospinal fluid pressure of 700 mm water which fell to 30 following the removal of 10 cc of yellow cerebrospinal fluid. Following this and the administration of 150 cc of 50 per cent glucose intravenously his pulse rose to 80 and blood pressure to 155/100. One and one half hours later a similar collapse occurred. Two hundred cc of 2 per cent magnesium sulphate solution was given intravenously with slight general improvement and a rise of blood pressure to 130/90. However circulatory failure set in his lungs filled up and he died twelve hours after the operation. Autopsy showed no further subdural bleeding.

Cerebral Subdural Hematoma in a Patient Who Had Been Committed to a Psychopathic Hospital as 'Alcoholic Psychosis' and Who Completely Recovered Following Removal of the Hematoma. No 62 *A case of right cerebral subdural hematoma following a fall on the street. Development of mental symptoms that led to commitment to a psychopathic hospital for an observational period. Admission on medical service as lead encephalopathy. Operative removal of right cerebral subdural hematoma with discharge free of symptoms seventeen days later.* This forty seven year old white male house painter was transferred from the medical service to the neurosurgical service November 22, 1933. He was a known chronic alcoholic. On October 20, 1933 he was brought home drunk following a fall on the street which had caused a laceration of his scalp. The following day he was sent by the police to a psychopathic hospital on account of disorientation and confusion. During the following two weeks at this hospital he became increasingly stuporous. Stippling was found once in his red blood cells and following the development of a left hemiplegia he was transferred to the Boston City Hospital on November 20, 1933 as a possible lead encephalopathy. On the medical service the stippling could not be confirmed but a lumbar puncture yielded yellow fluid under a pressure of 200 mm water. He did have an anemia which however, proved to be due to

fifteen years of bleeding hemorrhoids. On transfer to the Neurosurgical Service he was in coma with a flaccid left hemiplegia, hypertonic right arm and leg, bilateral hyperactive tendon reflexes, a right Babinski and a dilated left pupil. His blood pressure was 154/94. A right subtemporal decompression was made and a partially liquefied subdural hematoma covering the frontotemporal region was removed. The subarachnoid space contained yellow fluid and the cortex was colored dirty brown and was compressed. The fluid clot contained 10631 mg per cent of protein and microscopic examination showed the solid clot to be that of a well-organized subdural hematoma. He was discharged to the surgical side for treatment of his hemorrhoids free of all other signs and symptoms seventeen days later.

Subdural Fluid Abnormal Bridging Vein and Epileptiform Seizures after a Four Year Latent Period No 34 *A case of right cerebral subdural fluid associated with delirium after a four year latent period. Exploratory craniotomy with drainage of the subdural space division of an abnormal "bridging vein" and relief of symptoms to date for one year.* This thirty-one year old white male was admitted on April 1, 1933, because of attacks of headache associated with delirium and unconsciousness. These have been present at infrequent intervals for the past one and a half years. Six years ago he was unconscious for two hours following an automobile accident in which he sustained a lacerated wound of the scalp. On admission he stated that he was unable to work on account of his attacks. Neurological and physical examinations were negative except for a scar in the right parieto-occipital region and hyperesthesia and atropognosis on the left. During an attack in the hospital he complained of numbness of the left side, inability to move his left leg and weakness of his left arm. Lumbar puncture was not done. On April 17, 1933, a right parieto-occipital bone flap was turned down exposing a dura that did not pulsate and from beneath while from the subdural space a considerable quantity of yellowish fluid was collected. This had a protein content of 140 mg per cent. After the subdural space was emptied the brain began to pulsate and exploration of the cortex disclosed a large venous connection between the dura and the posterior parietal subcortical region which anchored the cortex at this point. This was divided and the flap replaced. The patient made an uninterrupted recovery except for a slight necrosis of the posterior medial edge of the scalp flap and has remained free of attacks to date, having been discharged from the hospital ten days after operation.

Subdural Hematoma Associated with Increasing Irrationality and Disorientation Culminating in Active Delirium and Complicated by Extreme Therapeutic Toxic Dehydration following Operation *See under postoperative complications case No 10*

UNUSUAL OBJECTIVE SYMPTOMATOLOGY

Right Hemiparesis and Hemianesthesia With Choking of Right Disc But Without Any Speech Difficulty *Removal of Subdural Hematoma from the Floor of the Left Middle Fossa With Subsequent Discovery that Patient Was Left Handed No 33* *A case of left temporal subdural hematoma following an automobile accident. Left subtemporal decompression and removal of the hematoma after patient had failed to improve under lumbar puncture and dehydration therapy with complete relief of symptoms.* This twenty-six year old white male was injured in an automobile accident on March 31, 1933. He was unconscious and had a lacerated wound of the scalp. Following eight lumbar punctures in six days he regained consciousness but complained bit-

terly of a severe headache. These punctures all showed bloody fluid under pressure varying from 450 to 250 mm water. On this day he was admitted to the Neurosurgical Service being referred by Dr. B. Gallagher of Waltham. Examination showed an apathetic man with slight right-sided weakness and right-sided hypesthesia. There was very early choking of the discs. The blood pressure was 120/40. The following day a left subtemporal decompression was made and through this a considerable quantity of bloody subdural fluid removed. This was not examined chemically. Because this failed to give the expected relief of the intracranial tension a further search was made and a large subdural clot evidently originating from a lacerated area in the adjoining cortex was found lying on the floor of the middle fossa beneath the temporal lobe. This was removed with return of the intracranial pressure to normal. The patient was discharged relieved and free of symptoms eighteen days after operation.

Decreased Cerebrospinal Fluid Pressure in a Case of Bilateral Cerebral Subdural Hematomata No 57 *A case of bilateral cerebral subdural hematomata associated with confusion of the brain and unilateral dilation of the pupil following an injury during a period of acute alcoholism.* This fifty-one year old white male was admitted to a general surgical service in what was believed to be an alcoholic stupor on October 13, 1933. He had a lacerated wound of the scalp which was sutured. A lumbar puncture was reported as showing normal fluid under normal pressure. The next day he was conscious and was up and about the ward but was noticed to be mentally abnormal. He was restless with irrelevant speech and tended to avoid the other patients. Sixteen days after admission he suddenly became deeply unconscious. A lumbar puncture showed a pressure so low as not to be measurable though old bloody fluid was obtained by suction. Examination showed a dilated right pupil, a bilateral spasticity of the extremities with increased reflexes, ankle clonus and Babinski's. The blood pressure was 150/95 and the pulse 88. A second lumbar puncture eight hours later was similar to the previous one. This hypotension was believed to be due to dehydration from his failure to drink enough liquid. Blood and spinal fluid Kahn's were negative. He was transferred at once to the Neurosurgical Service and operated within an hour. A left subtemporal exploration was made with the resultant escape of yellow fluid and clots from the subdural space with a resumption of pulsation of the cortex. A similar exploration was carried out on the right and enlarged to the size of a decompression. Through this was removed an encapsulated partially liquefied subdural hematoma which covered the entire lateral surface of the hemisphere. The liquid portion had a protein content of 8510 mg per cent and microscopic examination of the walls was reported as showing an organized subdural hematoma. The brain was confused. He remained unconscious until his death. Two days after the operation he developed left-sided convulsions and four days postoperatively a lumbar puncture showed a pressure of 125 mm water. The convulsions continued, his circulation began to fail and he died from this latter cause on November 4, 1933, six days after operation. Autopsy showed his brain damage to be much more extensive than had appeared at operation with no further significant subdural bleeding. The cause of death was given as brain injury.

THERAPY

Right Cerebral Subdural Hematoma Not Found Because of Failure to Explore Both Sides of the Skull

No 43 A case of right cerebral subdural hematoma associated with sudden unconsciousness during imprisonment for a charge of drunkenness Left subtemporal exploration—nothing found Death Subdural hematoma on right This sixty seven year old white male was transferred from the jail on August 8, having been imprisoned seven days previously on a charge of drunkenness. He had been found unconscious on the floor of his cell after having been reported as well two hours previously. On admission he was deeply comatose with Cheyne-Stokes respiration, spasticity of all extremities with hyperreflexia, Babinskis and ankle clonus. There was an old bruise on his face. Lumbar puncture yielded bloody fluid under a pressure of 120 mm water. The blood pressure was 220/120, pulse 100 and of poor quality. A left temporal exploratory trephine was made which showed nothing but a tense edematous, non pulsating brain. The right side was not done as it was hoped that his condition would improve and he could be again operated upon later. His condition continued to get worse however and he died without regaining consciousness three days after operation. Autopsy showed a large right cerebral subdural hematoma.

Death Due to Primary Incomplete Removal of a Right Subdural Hematoma No 41 A case of right cerebral subdural hemorrhage from a contused brain which was operated upon twice, the removal having been incomplete after the first interference Death followed the second operation This thirty-eight year old white male was brought to the hospital by the police because of presumed intoxication and a scalp wound on July 16, 1933. The wound was sewed up and he was sent home with his brother. He was brought back in deep coma the following day and admitted to the general Surgical Service. Two lumbar punctures showed bloody fluid under a pressure of 175 mm water. He was delirious and required restraint. He was transferred to the neurosurgical service at once and operated upon within three hours. A small right subtemporal decompression was made and a clot removed from the exposed subdural space. The left side was also explored but no pathology was found. He was markedly improved for two days followed by a rise in intracranial pressure renewed stupor and respiratory irregularity. He was at once taken to the operating room and the left side reopened with negative findings. The right side was then reopened and the decompression and dural opening enlarged. This permitted more complete exploration and resulted in the discovery and removal of 30 to 50 cc additional clot that had been missed at the previous exploration. The patient continued to go downhill and died five hours after the operation from acute cerebral edema and circulatory failure. Autopsy revealed no new pathology.

POSTOPERATIVE COMPLICATIONS

Acute Rapidly Advancing Postoperative Edema—see section on "Subjective Symptomatology" case No 44

Therapeutic Postoperative Dehydration Made Necessary by the Occurrence of Acute Postoperative Edema. No 10 A case of right cerebral subdural hematoma resulting from a contusion of the brain caused by a fall. Operative removal rapidly advancing postoperative edema therapeutic toxic dehydration, recovery This thirty five year old white man was admitted to the neurosurgical service on Feb 21 1933. He was injured on Feb 10 1933 following a fall of fifteen feet onto a concrete floor. He was unconscious for nine hours during which time he was taken to another hospital. On regaining consciousness his head was x-rayed found to have no visible fracture, following which he was discharged to his home on Feb 12 1933 with a diagnosis of 'concussion'.

Since then to the present he had had increasingly severe occipital headache and increasingly frequent and prolonged periods of irrationality. On admission he showed early choking of the discs, nystagmus, stiffness of the neck and increased tendon reflexes on the left and dilated left pupil. Lumbar puncture revealed bloody fluid under a pressure of 260 mm water. For three days he became progressively more disoriented and delirious and finally reached a stage where it was almost impossible to control his activities. On February 25, 1933 a bilateral exploratory subtemporal trephine was made, the left side being done first. The brain was not pulsating but otherwise no pathology was found on this side. On the right side the trephine hole was enlarged to a decompression and a small temporoparietal "currant jelly" subdural clot together with a considerable quantity of yellow subdural fluid was removed. The source of the bleed could not be found. For twenty four hours following the operation he was much improved but the next day he began to get restless and delirious again. At this time his temperature got to 102° and it was noted that his fluid intake had ranged between 1750 and 3000 cc in twenty four hours. His intracranial pressure was normal and his decompression flat and pulsating. On March 3 his fluid intake was raised to 7500 cc the two preceding days having been pushed to 5000 and 6500 respectively. Coincidentally he became cooperative, conscious with a temperature of 100° and ceased being incontinent. Two days later his temperature was normal, he was oriented and mentally clear, his fluid intake having in the meantime been kept between 6000 and 6500 cc in twenty four hours. From that time his progress was uninterrupted and he was discharged relieved and symptom free March 21, 1933, twenty five days after having been operated upon.

SUMMARY AND CONCLUSIONS

- 1 Subdural hematoma occurs in about one out of every six cases of craniocerebral injury
- 2 Subdural hematoma may be an expanding lesion. In such cases there may be a latent period during which symptoms are absent until the intracranial pressure begins to rise above normal
- 3 The signs and symptoms caused by subdural hematoma are the same as those caused by any other major brain injury. Patients suffering from the latter get better under appropriate non operative treatment. Those suffering from the former condition, however, in the large majority of cases die unless operated upon
- 4 The certain presence of a subdural hematoma can only be determined by bilateral exploratory subtemporal trephine
- 5 Treatment of subdural hematoma can be best carried out through a subtemporal decompression. The entire clot should be removed, drainage should be provided and irrigation in the presence of a contused or lacerated cortex should be avoided
- 6 Postoperative edema is a common and serious complication. Treatment should be early and vigorous and include dehydration, lumbar puncture drainage caffeine and two per cent MGSO₄ intravenously, and appropriate measures to lower the body temperature.

7 Without surgical interference the mortality of twenty-two proved cases of subdural hematomata was 100 per cent. With operative treatment as outlined the mortality in a series of thirty-nine cases was 41.2 per cent.

8 The artificial segregation of certain of the so-called chronic forms of this disease should be abandoned. It has come about only because of our failure to recognize the same condition at the time of its original production.

9 A bibliography covering the ten-year period from 1924 to 1934 and a group of typical case histories are appended.

I am happy to have this opportunity to gratefully acknowledge the stimulus and assistance I have received from Dr. Timothy Leary, Medical Examiner of Suffolk County, Boston, Massachusetts. Without his stimulus the work would never have been undertaken; without his help it could never have been completed.

DISCUSSION

DR. SAMUEL C. HARVEY, New Haven Conn. I am glad to have the opportunity of discussing this most important paper of Dr. Munro's.

We have been accustomed in the past, I think, to segregate subdural hematomata into two rather sharply defined groups: the one showing the acute middle meningeal hemorrhage syndrome, the other the so-called chronic subdural hematoma with which the patient returns to the surgeon with a cystic type of lesion.

The point of Dr. Munro's paper which I take to be peculiarly significant is the fact that there is an intermediate or bridging type of hematoma which should be picked up in the acute phase and treated at that time. This is very easily said but done with much more difficulty.

Judging from his charts as well as from my own experience the signs and symptoms of this condition are very variable and transitory. They can not be built up into a clear-cut clinical picture. One must depend to a great extent on the course of events. If the patient is improving and continues to do so, he is probably not suffering from a serious subdural hemorrhage. On the other hand if he does not improve promptly or if his progress is downhill then he very likely is. Even then it is difficult to differentiate this condition and the severe "commotion" (if I may use the term) of the brain which may likewise carry the patient progressively downhill.

It is true without doubt that all of us have overlooked the more acute phases of the subdural

hematoma, and it is likewise true that instances of local injury coming to necropsy show a disturbingly high ratio of subdural hemorrhage. Whether all these patients die from such hemorrhage is another question. In many, the underlying fatal pathology is the severe primary injury to the brain itself.

Nevertheless, Dr Munro's paper is a very enlightening contribution and should assist us in discovering a considerable number of these lesions and subjecting them at once to operative treatment.

DR GEORGE A MOORE, Brockton, Mass. Gentlemen, I am not going to attempt to discuss Dr Munro's very interesting paper. This is a specialized zone of surgery that I have felt is not at the present time in the field of the general surgeon. It has been my pleasure to hear Dr Munro discuss this subject once before at the City Hospital and at the same time see Dr Timothy Leary's series of brains with hematomata that were found at autopsy.

I am reminded of what Dr Harvey Cushing said at one time when he was giving a clinic on acromegaly. He stated that it was only a comparatively few years ago that the field of thyroid surgery was limited to a very few specialists in that line of work, but we now see thyroids operated upon by a great many men doing general surgery. He predicted that in a few years we may see surgery of the pituitary gland taken over by the general surgeon.

At present many men in general surgery are not operating on subdural hematomata. Dr Munro has placed special emphasis upon the number of unrecognized cases with this condition which have been observed at the City Hospital. It would appear that the general surgeon should be more on the alert in the care of cases of head injury to recognize symptoms of intracranial hemorrhage.

Of especial significance in Dr Munro's statistics was the large number of patients with abnormal physical signs. There were some thirtysix patients with motor symptoms and about forty patients with mental symptoms. With more painstaking study we should recognize these symptoms in more cases and get these patients into the hands of the neurosurgeons in time to decrease the mortality that now exists.

DR W J MIXTER, Boston, Mass. I think this work of Dr Munro's is very valuable. He has created a lot of interest in the subject which has been reflected not only among the people who are perhaps more interested in neurosurgery but also I think, among the men who are doing general surgery.

I disagree with Dr Moore a bit. I think the general surgeon has to handle a number of these cases because many times the general surgeon will find a case of subdural hematoma among the acute cases in his practice.

We have planned at the Massachusetts General to have our general surgical house officers see the traumatic neurosurgery so far as we can and not confine it to the neurosurgical house officers because we feel that the general surgeon must handle a great deal of the traumatic neurosurgery perhaps not the cases that run along and can be handled as late cases but the acute immediate surgical emergencies.

So far as type of operation goes Dr Munro has well stated that there is a great difference of opinion as to the methods of attack, and I should agree absolutely with him that the subtemporal decompression was the best general method to use. In some instances the trephine opening with evacuation of the fluid blood will work well. I think the osteoplastic flap as a general rule is unnecessary. The subtemporal decompression can be extended either forward or backward and works very well in

these cases. It has seemed to me that there were a certain number of the subdural hematomata that were nontraumatic and arose probably from the small aneurysms of the circle of Willis, much in the same way that the spontaneous subarachnoid hemorrhages do. That is probably not nearly so common as the traumatic origin but I believe does occur in certain instances and I should like to ask Dr Munro for his opinion.

DR LUCIUS C KINGMAN, Providence, R. I. I have seen a number of war wounds of the head which resembled the cases under discussion. The patients entered the base hospital about three days after injury. They would walk in with apparently a simple scalp wound. However, there would be a history of being knocked out at time of injury usually followed by nausea. By the next day they would complain of a restless night, some headache and nausea. With such a story we would open the skull and under the site of the bullet wound we would find a subdural hematoma and often some disintegrated brain. This would be washed out and all made immediate recovery. The after history is unknown. The indication for the operation was made entirely on the history.

DR CHARLES L SCUDDER, Boston, Mass. I have two thoughts in connection with this valuable and timely paper of Dr Munro. It used to be considered that the taking of various specialties out of the general surgical field diminished the usefulness of the general surgeon. It seems to me that Dr Munro has illustrated in this series of cases, as has already been pointed out, that the neurosurgeon specialist is contributing to general surgery data which may be of assistance to the general surgeon, he is not taking cases away; he is educating the general surgeon so that he may adequately and early treat the cases of subdural hemorrhage.

The other thought I have in connection with the paper, and I think Dr Munro has made a very important communication is the fact that Dr Munro stresses the point that for an accurate diagnosis an exploratory trephine opening often may be necessary. That is a very radical statement to make. It is accurate and true and I believe that it illustrates a distinct advance in the surgery of the head, that an exploration of the skull of the cranial cavity should be made under certain conditions for the purpose of making an accurate diagnosis of subdural hematomata. Dr Munro has contributed in this paper to the constructive advancement of surgery bringing to the general surgeon accurate information of an hitherto unrecognized rather common lesion. He has thereby made surgery more efficient. The advance of exploratory trephining under the conditions stated is an important step in the surgery of the head.

DR LYMAN ALLEN, Burlington, Vt. I should like to speak just a moment about a similar case, and first I want to say that I know nothing about subdural hemorrhages except those due to trauma. I think every general surgeon should realize the importance of recognizing the symptoms of traumatic head injuries such as slow pulse, high pressure, and so forth.

The case I wish to speak of is that of a laboring man who was lifting a large rock onto a truck. He slipped and the rock struck him on the nose and forehead knocking him down and stunning him. It broke his nose and bruised his forehead. When he was brought to the hospital his pulse and his pressure were normal and continued so for the next few days. The broken nose was fixed and he was walking around feeling perfectly well and had been transferred upstairs which we do with some

of our convalescents. He was about to go home when, at nine-thirty one night, he suddenly became unconscious, with stertorous breathing. His roommate called the nurse's attention to his breathing. His pressure was 238/130 and pulse 122. Repeated lumbar puncture showed bloody cerebrospinal fluid under increased pressure. He died three days later. We probably should have trephined, but did not. Autopsy showed a contusion of the right anterior frontal lobe with softening of the clot and rupture through into the lateral ventricle. There was no infection whatever.

I want to ask Dr. Munro what we could have done if we had trephined and had found the contused frontal lobe with softening of the clot.

I do feel that in these days of traveling sixty miles an hour around corners, the recognition by the general practitioner (to say nothing of the surgeon) of symptoms suggestive of brain injury is important. Such symptoms should be looked for carefully and repeatedly.

I also believe that a diagnostic trephine is probably safer for the patient in many cases than motor inactivity.

Dr. Munro: Dr. Allen, your case in my opinion, gets right to the crux of the situation. There is no question but that most of the head injury cases particularly these difficult diagnostic problems are going to be left on the doorstep of the general surgeon. The neurosurgeon or the specialist, the neurologist is going to see only those who live long enough to let him get to them; those who can afford to pay for a consultation, and those whose families will recognize and cooperate with the general surgeon in recognizing the value of getting in a specialist whatever that value may be.

On the other hand there are certain responsibilities that necessarily rest on the general surgeon if he is going to take on this work and I think Dr. Allen's question brings up perhaps one of the most important of those responsibilities. This has to do with the equipment in the operating room.

I operate occasionally outside of Boston not by preference but by necessity and I have yet to go into an operating room in a city outside of Boston that has been properly equipped to handle efficiently these acute surgical emergencies that occur as a result of head injuries and the usual most obvious lack of equipment is the lack of some efficient method of suction. That seems like a common or

garden variety of thing to have. The hospitals I happen to have seen have been equipped with the tonsillar suction apparatus where the suction is made by a pump run by an electric motor, and about the time when you reach the end of the first hour and a half and when you really want to use the suction most, all the bearings on the pump and motor freeze and you are left without any suction at all just because you have used it incidentally when you didn't really need it.

I don't believe anybody can handle efficiently such a case as you instance, without suction, on the other hand, with suction you can operate on that type and remove by suction all the soft clot and the contused brain and give these patients a very much better chance of recovery than if you merely open the skull and the dura and leave behind this mass of foreign protein to cause further trouble to the patient's already complicated life.

Dr. Mixer points out that there are cases of subdural hematoma that are non-traumatic. There is no question that that is true. Henschen, whom I mentioned, and who is a Swiss, had quite a list of these cases in his paper. He had combed the literature fairly thoroughly and among other things he mentioned arteriosclerosis and the multiple aneurysms that you spoke of.

I am very much interested to hear of your cases, Dr. Kingman. It is too bad they are not in the literature. Perhaps the Surgeon General and you could get them there, because I think any authentic series of cases of proved subdural hematomata that present a constant history is very well worth while.

My impression from the cases I have seen is that the historical side is a very difficult thing to evaluate and I feel the best that I can do is to say that these cases had a severe injury to the head and perhaps subdural hematoma should be included among the diagnoses.

I am very much struck by the fact that the more one interests oneself in the problem of subdural hemorrhages the more subdural hemorrhages crop up. I and my then associates were practically kicked into this investigation by Dr. Timothy Leary, the Medical Examiner. He was finding subdural hemorrhages we had missed over and over again and it finally got to the point where we were so embarrassed we could not attend his conferences. In self-defense we looked into the matter from the clinical side and as I say, the more we investigated, the more subdural hematomata were found.

THE CLASSIFICATION OF THE CAUSES OF BLINDNESS

International agreement on the classification of the various causes of blindness was sought by delegates from America, Great Britain, and many European countries at the annual meeting in Paris May 14 of the International Association for Prevention of Blindness.

That statistics on the causes of blindness which can be understood by laymen constitute an important factor in the prevention of blindness was pointed out by Professor F. de Lapersonne of the University of Paris, president of the Association.

Dr. Park Lewis of Buffalo, N. Y., vice president of the Association urged that in addition to classifying the causes of blindness, an effort should be made to classify the extent or degree of blindness when vision exists but not in sufficient amount to be of practical use.

More than fifty different etiologic classifications of

blindness are listed in a report submitted by Lewis H. Carris of New York City, managing director of the American National Society for the Prevention of Blindness. "The question of a satisfactory classification of the causes of blindness," said Mr. Carris, "has occupied the attention of the American Committee on Statistics of the Blind for the past three years. The Committee represents the points of view of ophthalmology, public health work for the blind, prevention of blindness and social statistics. It is interested in social and economic as well as medical facts."

Among the major causes of blindness included in the American report are infectious diseases such as diphtheria, measles, opthalmia neonatorum, scarlet fever, syphilis, trachoma and tuberculosis, traumatic and chemical injuries sustained in war, industrial accidents, traffic accidents and surgical procedure and congenital and hereditary causes. *Excerpts from The Bulletin of the National Society for the Prevention of Blindness, Inc.*

ADENOCARCINOMA OF THE STOMACH*

Case Occurring in a Man Twenty-seven Years of Age

BY ROBERT L. PATTERSON, M.D.,† AND ROBERT E. GROSS, M.D.†

HOLMES and Hampton¹ have reviewed evidence to show that chronic ulcerations in the prepyloric area of the stomach usually represent carcinomatous lesions. It was the opinion of these authors that all ulcers at this site should be subjected to surgical exploration because of the frequency with which neoplasm is encountered. The following example of carcinoma of the stomach tends to support this belief. This case also illustrates the difficulty which may arise in differentiating a benign prepyloric ulcer and a cancer in this region. Gastric carcinoma has been occasionally reported below 30 years of age and the following report again emphasizes that the lesion may be found in the third decade of life.

History. The patient was a 27 year old white man who entered the Medical Service of the Peter Bent Brigham Hospital on June 28, 1933 with a chief complaint of three attacks of epigastric pain and vomiting during the previous six months. The onset of this illness began January 1, 1933 following excessive indulgence in alcohol. This first attack lasted one week and was characterized by recurring gnawing pain in the epigastrium and beneath the right costal margin which was relieved by vomiting. The pain had no relationship to eating. During this week he vomited all solid food that was taken, but no fresh or changed blood was noticed in the vomitus. His symptoms completely subsided on a diet of milk and bismuth powders. Gradually he discontinued the bismuth and returned to his regular diet.

He was then symptom free for over three months until he again indulged in alcoholic beverages. Following ingestion of alcohol in April, 1933, the epigastric pain and vomiting returned. Pain and vomiting persisted for several days until he voluntarily returned to a milk diet and bismuth powders. This pain during this attack appeared about an hour after eating and was relieved by vomiting and also by taking baking soda.

He was then in fair health until June 23, 1933. At that time the third major attack began which was similar in nature to those previously described. He was referred to the Hospital because of persistence of symptoms. His stools during the previous six months had occasionally been black. During this half year period he had lost 25 pounds of weight.

The family and past histories were irrelevant.

Physical Examination. The patient was a well developed but poorly nourished young man in little apparent distress. Temperature 98.6°. Pulse 92. Respirations 20. Blood pressure 140 systolic 70 diastolic. Except for evidence of weight loss the examination was negative. There was no abdominal distention, tenderness, mass or spasm.

Laboratory Data. Hemoglobin 95 per cent (S). Red cell count 4,500,000. White cell count 10,700. Urine negative. Blood Wassermann negative. Stools had positive benzidine and guaiac tests for occult blood. Gastric analysis showed free acid equivalent to 60 cc. of 0.1 normal sodium hydroxide and total acid equivalent to 100 cc. 0.1 normal sodium hydroxide.

*From the Surgical and Pathological Services of the Peter Bent Brigham Hospital, Boston, Massachusetts.

†Patterson, Robert L.—Interne Surgical Service, Peter Bent Brigham Hospital. Gross, Robert E.—Interne Pathological Service, Peter Bent Brigham Hospital. For records and addresses of authors see "This Week's Issue," page 1154.

Hospital Course on Medical Service. Cholecystograms by the intravenous method showed a well-filled and normally functioning gall bladder. Gastrointestinal x-ray series were taken. Fluoroscopy showed the rugae in the prepyloric area to be thickened with an irregularity of the wall at this site. The stomach was low and hypotonic. The duodenal cap filled fairly well and appeared normal in contour and

FIG 1. Roentgenograph of stomach. The two arrows indicate the raised margins at the edges of the lesion on the lesser curvature. Between the arrows is the crater of the neoplasm. Fluoroscopy showed that no peristaltic waves passed across this prepyloric area.

position. There was approximately a 5 per cent residue in the stomach after six hours. These studies suggested a prepyloric ulcer.

During the twelve days that the patient remained in the hospital he rapidly became symptom free. For the first seven days a first week Sippy régime was prescribed and for the remaining period, a fourth week Sippy régime was employed. Free acid was well controlled in aspiration material (free acid 0.5, total acid 7.28). He was discharged July 10, 1933.

Subsequent Course. For the following two months there were occasional recurrences of very mild epigastric distress. He was taking a normal diet but used three to five powders per day. He gained 15 pounds in weight. X-ray examination was repeated on September 12, 1933 by Dr. Merrill C. Sosman. This again showed the irregularity in the prepyloric area extending up from the pyloric sphincter about five centimeters along the lesser curvature. At the incisura there was a definite filling defect with a central crater (fig. 1). No peristalsis passed through

this zone. The gastric rugae were enlarged. There was no six hour residue. The duodenal cap was normal. The findings suggested neoplasm rather than ulcer. Exploratory operation was recommended.

Second Hospital Admission. The patient entered on the Surgical Service. Physical examination was negative, except for very slight discomfort produced by deep palpation in the mid epigastrium.

Operation was performed on September 23, 1933, by Dr. Robert Zollinger. The abdomen was explored through a midline upper abdominal incision. A mass about 7.5 cm in diameter was found along the lesser curvature of the stomach, extending up from the pylorus. The stomach was entirely mobile. There

The patient was discharged on October 22, 1933, in excellent condition. When last seen in March, 1934, he was symptom free and in good health.

PATHOLOGIC EXAMINATIONS

Gross Description. The resected portion of the stomach measured 16 cm along the greater curvature and 8 cm along the lesser curvature. Two cm. of duodenum were included with the specimen. The tumor presented on the mucosal surface as a large centrally ulcerated mass 45 mm in length and 35 mm in width (fig. 2). The distal margin of the neoplasm reached just to the pyloric sphincter. The margins of the tumor were raised 8 to 10 mm above the general plane of the gastric mucosa. About one

FIG. 2. Photograph of portion of operative specimen. The neoplasm appears with rounded raised edges and a depressed central crater. The pylorus is at the right of the photograph.

were no palpable glands along the lesser curvature or in the gastrohepatic ligament. No nodules were felt in the liver or elsewhere in the abdomen. The gastric mass was resected with a wide margin, removing over half of the stomach and about two centimeters of the duodenum. The remaining stomach and duodenum were joined by a Horsley modification of the Billroth I type of anastomosis.

The patient made an uneventful recovery. Gastric analysis on October 18, 1933, 25 days after operation gave the following results:

	Free Acid (cc 0.1 N NaOH)	Total Acid (cc 0.1 N NaOH)	Gualac Test
Fasting	0	20.5	Neg
20 minutes after test meal	0	12.0	
40	0	7.0	
80	0	2.0	
120	0	10.0	
30 minutes after 1 mg of histamine	3.0	25.0	

half the circumference of this rim was rounded while the remaining half was irregular, jagged, necrotic and hemorrhagic. The crater was 35 mm long and 30 mm wide. It was 12 mm in greatest depth. The deepest portion of the crater projected into the musculature of the stomach wall. The mucosa about the neoplasm was edematous and the musculature was hypertrophied proximal to the tumor. On the exterior of the specimen the serosa was smooth and unbroken. There was no neoplastic invasion of the serosa, the included portion of the gastrohepatic ligament, or the regional lymph nodes.

Microscopic Examination. Sections showed an adenocarcinoma. The tumor replaced the mucosa and submucosa and partially invaded the muscularis. There was no involvement of the outer muscular coats, the serosa, or the regional lymph nodes. Where the tumor was poorly differentiated the cells were large, polyhedral, and varied greatly in size and shape. The nuclei were ovoid, had a fine chromatin material and often contained two or three nucleoli. Most of the tumor was well differentiated and tall columnar cells formed acini and glandular structures of varying size and shape. Mitotic figures were often seen and two or three often could

be found in a high dry field. The stroma was of only moderate amount. There was a moderate inflammatory reaction throughout the tissue. On the surface facing the gastric lumen there was a fibrino-

stomach occurring in a man 27 years of age. The symptoms, clinical course, and relief on ulcer treatment suggested that the lesion was of

FIG. 3 Photomicrograph of gastric neoplasm $\times 110$. The tumor is here differentiated into acinar and glandular structures.

hemorrhagic exudate. The picture was more suggestive of primary gastric carcinoma than a carcinomatous formation at the site of a previous ulceration.

SUMMARY

Report is made of an adenocarcinoma of the

a benign type, but the location in the prepyloric area aroused suspicion of gastric carcinoma. Resection was performed. The patient is in excellent condition six months after operation.

THE METABOLISM OF LEVULOSE*

IV The Hepatic Influence On The Utilization of Galactose and Levulose

BY ALLAN WINTER ROWE, PH D,[†] MARY A. McMANUS, A B,[†] AND ALBERT J. PLUMMER, A M[†]

IN an earlier communication²¹, the authors discussed certain general aspects of the metabolism of levulose as indicated by response to a provocative levulosuria. The present paper deals with the hepatic factor as it influences the

utilization of this sugar, for purposes of contrast and amplification, the galactose tolerance has also been measured for the same group of subjects. There is an historic basis for comparing these two sugars as within the last thirty years each has been warmly advocated as the best approach to a measure of liver function and their several claims equally positively denied. Strauss²⁸ in 1901, influenced by the previous observation of Sachs²² that dehepatized frogs could utilize glucose and galactose but not levulose, developed a test for liver function

Presented at the Forty-Fifth Meeting of the American Physiological Society Cincinnati April 1933.

[†]Rowe Allan Winter—Director of Research Evans Memorial Massachusetts Memorial Hospitals. McManus Mary A.—Assistant in Biochemistry Evans Memorial Massachusetts Memorial Hospitals. Plummer Albert J.—Fellow in Biochemistry Evans Memorial Massachusetts Memorial Hospitals. For records and addresses of authors see This Week's Issue page 1144.

based upon provocative levulosuria. Four years later, Bauer² suggested the substitution of galactose as the test sugar, and during the next ten years a fairly extensive literature, reviewed in part in the paper already cited²¹, affirmed and denied the advantages of each sugar as a test for liver function. Yet again, a few years later, the development by Folin⁵ and others of more precise methods for blood sugar analysis practically reopened the question, and again a group of reports appeared championing the one as opposed to the other.

Unfortunately, blood sugar curves lack a clarity of outline and are insusceptible of that quantitative interpretation which is the basic criterion of the value of a function test.¹⁻⁶ Most recently, a group of communications has appeared canvassing the merits of galactose¹⁰⁻¹⁸ and the question has been reopened by Shay and his associates²³⁻²⁵ reverting to the technique originally outlined by Bauer.⁴ Unfortunately when Bauer first described the test, the carbohydrate paradox (Allen¹) had not been recognized, and the author set as the evidence of an exceeded tolerance the arbitrary limit of a galactosuria of 3 grams or more with a test meal of 40 grams. Without adding further to the dialectic in this somewhat controversial field, it may be said that within the wide confines of the 3-gram limit, major fluctuations in tolerance can occur and be merged to an uninformative parity of implied normality. Even in the early days of the test, this lack of definition was recognized and the limiting boundary was lowered to 2 grams¹⁵, to 1 gram²¹, and in a number of instances⁹⁻¹²⁻²² to the positive response to a qualitative test. This latter procedure was further refined by lowering the test meal to 30 grams²⁰⁻³⁰ and even to 20 grams.⁷

The earlier work, in part at least through a failure to recognize the disturbing influence of the carbohydrate paradox, also ignored the sex difference later described by one of us.¹⁷⁻¹⁸ This has recently been denied by Harding and Moberley⁸ on the basis of an essentially different technique. Their results are qualitatively in accord with those of the senior author; they prefer to ascribe the different response of the sexes to a difference in the degree of diuresis which the sugar excites, this would seem to be equally a phenomenon governed by the sex of the subject.

During the past ten years, the senior author and his associates have been studying the metabolism of galactose from a variety of standpoints and a series of reports has appeared in the literature.¹⁷ One of the more recent¹⁷⁻¹⁸ has dealt specifically with the hepatic element as a factor of influence in the metabolism of this sugar. In general, hepatic dysfunction exercises a depressing influence on the utilization capacity of the individual, a certain number, however with-

out significant complication, showed normal or even increased power to utilize this sugar.

The present study reports the results from a somewhat smaller but equally representative group whose tolerance for both sugars was determined during the course of an elaborate diagnostic study. The technique of administration, the analytical procedures and the needful precautions have already been discussed in the preceding paper.²¹ The subjects utilized for the study are recorded in the first table. All of the patients had a demonstrated hepatic dysfunction of some type, in addition, one half had some complication usually influencing sugar tolerance.

TABLE I
PRIMARY ETIOLOGY

Group	Number
I Hepatic Dysfunction, uncomplicated	35
II Toxic Pregnancy	22
III Thyroid Failure	11
IV Miscellaneous	
Pituitary (dysfunction)	3
Ovary (hypofunction)	3
Abortion	1
Cancer (liver)	2
Syphilis	2
Psychosis (alcohol)	1
	— 12
Total	80

Group I was composed of individuals with demonstrated hepatic dysfunction of varying causes and types. Group II was composed of pregnant women with toxemia, all demonstrating an hepatic factor.¹⁰ Group III was composed of patients with thyroid failure complicated by hepatic disorders, an association of relative frequency.²⁰ Group IV is a miscellaneous group, half of whom show an endocrinopathy while the other half present other types of morbidity all complicating or associated with a primary hepatic status. These latter were selected as the complications which they present are known to influence the galactose tolerance. The basic data of sex and age are grouped in table II.

TABLE II
SEX AND AGE

Group	I	II	III	IV	Total
Sex					
Male	10	0	2	5	17
Female	25	22	9	7	63
Age					
High (yrs)	71	44	51	60	71
Low (yrs)	13	20	14	12	12
Average (yrs)	40	32	37	32	36

Irrespective of the overweighting deriving from the group with toxic pregnancy, there is

a very definite preponderance of females. The age range shows a wide scatter, that of the pregnant women alone exhibiting the narrower boundaries intrinsic in their physiological status. The group averages show a reasonable parity.

Certain other data deriving from history or examination bear more directly on the common factor of the series, i.e., the hepatic element. Nearly 10 per cent of the series had had earlier gall-bladder disease leading to surgical intervention, while double that number at the time of study gave clear-cut evidence of gall-bladder pathology on radiographic examination. In like manner, past or present appendicitis was a common datum and other pathology of the gastrointestinal tract was reported with significant frequency. Hepatic enlargement was demonstrated in six of the group. Table III presents a convenient summary of these several pertinent features on the basis of relative frequency.

TABLE III
SUMMARY

Datum	%
Gall Bladder	28
Appendix	39
Abdominal and Pelvic Pathology	34
Hepatic Enlargement	8

The several factors susceptible of quantitative expression associated with the carbohydrate exchange fall broadly into three categories, namely, blood, urine, and respiratory exchange. In the first, blood sugar curves, as already noted above, fail to offer a reliable quantitative approach, and with levulose the changes in level produced by even massive test meals are very small. Control blood sugar levels are pertinent, however, as hyperglycemia may produce abnormal urine findings. In the second group glycosuria as such indicates a disturbance of the sugar metabolism although the factors capable of producing it are protean in their array. The tolerance test, as applied in this study rests upon evidences in the urine of an exceeded assimilation limit.

The third group of evidences, i.e., the respiratory exchange, has not been undertaken in these studies. Carpenter and his colleagues⁴ have shown definite and positive results with both the sugars and in the case of galactose⁴ have recorded an interesting difference in the response of the two sexes.

TABLE IV
BLOOD AND URINE RECORD

Datum	Group				Total
	I	II	III	IV	
Glycosuria	29%	23%	9%	25%	24%
Blood Sugar					
High (mg)	123	102	105	113	123
Low (mg)	69	70	85	65	65
Average (mg)	94	86	95	96	92

The influence of thyroid failure in raising sugar tolerance is suggested by the less frequent occurrence of glycosuria in this group (III). The low blood sugar average of Group II reflects the downward trend known to be associated with pregnancy. The hypoglycemic levels of the low records in Groups I, II, and IV may be interpreted in terms of the liver influence, the complementary high figures may be traceable to the emotional reaction to venipuncture, always a source of potential error. As it is, no significant hyperglycemic levels are recorded and the averages fall well within the strict range of the normal.

One special approach to the estimation of the levels of hepatic activity is found in the measurement of bile production following the technique of McClure and his associates¹¹. A few of the patients were unable to take the duodenal tube and so the record for this evidence falls a little short (14%) of completeness.

TABLE V
LIVER FUNCTION (McCLURE)

Datum	Group				Total
	I	II	III	IV	
Number examined	29	20	10	10	69
Color					
Brown (%)	14	5	40	0	13
Yellow brown (%)	4	10	10	30	10
Green (%)	10	5	0	10	7
Yellow (%)	72	80	50	60	70
% Below normal					
Furfural Index	86	80	70	100	84
Cholesterol	59	45	30	60	51
Pigment I	79	85	80	90	83
Pigment II	90	90	70	90	87

Of the four constituents measured, cholesterol is the least influenced by abnormal bile production. Further, low values are less frequently recorded in Group II where high blood cholesterol constitutes a characteristic feature of the basic condition¹², and in Group III where a similar condition may be regarded as possible¹³. So far as the biliary function of the liver is concerned, these figures leave no doubt as to significant hepatic abnormality in the members of this series. Other evidences, omitted in the interest of space conservation, are wholly supporting.

Turning now to the primary matter of this communication, the response of the series to galactose will first be considered. For purposes of orientation, it may be stated that the normal male tolerance level is 30 grams, while the response of the female is broadly influenced by her sexual status and ranges from 20 grams in the prepuberal years through 40 during the adult period of sexual activity to a slight decline (two thirds drop to 30 grams) after the climacteric. Pregnancy and menstruation lower tolerance while castration or severe

functional failure of the ovaries restore the tolerance level to 20 grams. Thus departures with the female can be mutually correlated only by expression in terms of percentage deviations, while the male does not show this fluctuation, for the sake of uniformity, relative values have been adopted throughout. The results of the galactose testing are collected in table VI.

TABLE VI
GALACTOSE TOLERANCE

Datum	Group				Total
	I	II*	III	IV	
Above normal (%)	0	5	0	8	3
Average amount	—	+100%	—	+33%	—
Normal (%)	6	80	36	17	31
Below normal (%)	94	15	64	75	67
±0 to -33%	23%	0	36%	8%	17%
-34% to -67%	43%	15%	18%	42%	32%
More than -67%	28%	0	9%	25%	18%

*Two cases not tested

While it is generally conceded that disturbed hepatic function has a depressing influence on the galactose tolerance, there is a complete lack of agreement as to the types of liver disorder influencing the test. Many of the reports fail to allow for the carbohydrate paradox, and thus individuals showing a marked depression are designated as normal because their galactosuria falls below an arbitrary value which could be produced in the normal individual only by massive supertolerance doses. In a recent paper by Roe and Schwartzman¹⁰ in which they report the administration of galactose on the basis of one gram per kilogram of body weight, the doses range from 44 to 75 Gm (average for 10 subjects, 63 Gm), and the amount recovered in the urine from 0.91 to 2.78 Gm, with an average of 1.67 Gm. Thus with relatively large supertolerance doses not one of the group surpasses the inexacting standard originally suggested by Bauer.²

While the tendency is usually downward¹¹⁻¹³, some uncomplicated liver cases show a normal and a few exhibit a definitely increased tolerance. Making allowance for all possible superimposed factors influencing tolerance and for potential errors, there yet remained six cases (4 per cent) with normal and seven (5 per cent) with increased tolerance. In the present smaller series of Group I, none of the patients studied showed an increased tolerance, 6 per cent were normal, and the remainder exhibited varying degrees of depression. Pregnancy lowers the galactose tolerance and in the later stages the prepuberal level of 20 grams is uniformly encountered in the normal.¹⁴ In this group, all of the members of which had definite evidence of hepatic abnormality, four-fifths of the entire series were normal, one case showed an augmented tolerance, and only the inconsiderable

remainder (15 per cent) gave evidence of a depressing hepatic influence. In Group III the augmenting influence of thyroid failure works in opposition to the usual depression of the liver dysfunction. The result is to give normal tolerances in one-third of the group. Finally, in the miscellaneous group (IV) one case with a bilobar pituitary failure, a condition which exerts the most powerful of known augmenting influences, overbalances the hepatic depression and shows the modest increase of 33 per cent above prediction. Further, two cases are normal and the remainder are all depressed. In other words, of the eighty cases represented, over half of whom present superimposed complications which ordinarily affect the galactose tolerance, 3 per cent are above normal, 31 per cent normal, and the remainder, two thirds of the entire group, exhibit the depression which is the usual response. The distribution is to be regarded as typical, certain implications will be discussed later in the text.

All of the patients in this series were also tested with levulose, using a sugar of the highest purity, a precaution of fundamental importance in tolerance testing with all sugars. Standards for normal levels with this latter sugar at present lack clear-cut definition, as the total levulose series is but a few hundred in number, and this includes both the normal and abnormal. The very high cost of the sugar, the larger amounts used in testing, the time factor for the complete diagnostic survey, and yet other inhibiting influences have prevented that completeness which is the ultimate goal. Enough work has been done, however, to warrant the establishment of approximate values for normal standards.

TABLE VII
NORMAL LEVULOSE TOLERANCE
(Values are approximate)

Condition	Positive Test Meal
Male adult	100 Gm
Female, adult	100-125 Gm
Female pregnant	50-100 Gm

While the values are at best approximate, several features are suggestive. First, there does not seem to be evidence of a clear-cut sex difference with this sugar, it is not precluded and a longer series may reverse the present impression. Secondly, while pregnancy produces a lowering in tolerance, it does not manifest itself so early and the decline is slower, the final relative level, however, compares favorably with that shown by galactose. Since the normal standards cannot be straitly delimited, it has seemed best to report the results of levulose testing initially in terms of the actual sugar dose which first produced a demonstrable levulosuria. Taking the tentative standards of 100-125

Gm to embrace both the normal male and female, Group I, the only sub series without extraneous sugar influencing factors, it is evident that 9 per cent are above and 71 per cent below the normal zone. The figures do not compare well with those from the galactose test where 94 per cent were depressed and but 6 per cent normal. Group II, with an even larger zone defining the normal, practically duplicates the distribution in the galactose test. Even if the 100-gram response were interpreted as an increased tolerance, 68 per cent of the series would still fall in the normal zone. In Group III with

Three of the four groups (I, II & IV) show an almost identical division with two cases in agreement for each failing in concordance. The sole exception, Group III, shows the same partition but in the opposite sense. This would seem to confirm the tentative opinion that the endocrine (thyroid) influence is not the same on the metabolism of the two sugars, qualitatively, at least, disturbed liver function seems to have a depressing effect on both sugars but in a slightly more pronounced degree with the galactose (65 per cent against 58 per cent).

DISCUSSION

A brief review of the findings of others may suitably preface the discussion of these results. Nine authors report a total of 525 normal individuals who have been given 100 Gm of levulose by the oral route, seventy-one, or 14 per cent, were reported positive to this dosage. Many of the subjects were the so-called "hospital normal," and further, as has already been noted in the text, the criteria for positive response are almost as numerous as the investigators. Strauss²⁸ the original proponent of the test used a qualitative demonstration of melituria, Frey⁷ regarded anything less than 0.1 Gm as normal, i.e., negative, while Wörner and Reiss²² adopted the more liberal limit of 0.7 Gm in the urine to define the normal. Our own results would make it seem probable that on the basis of the Strauss criterion the number receiving a positive report would be definitely augmented.

Nine articles in the literature report a total of 217 pregnant women of whom 180, or 83 per cent, were positive with an oral test meal of 100 grams. Within the limitations noted above for the "normals", these figures would seem to be in general accord with our own results.

Turning to the reports on liver function, seventeen papers report 954 cases, of whom 649, or 68 per cent, were positive to 100 grams of levulose. Superficially there would seem to be a rough agreement with our own figure of 58 per cent, closer analysis develops a definite lack of concordance. With many of the reports based upon a more exacting standard of positive response than our own qualitative index, there are none the less 10 per cent more cases with a positive test than in our own small series. This figure would undoubtedly be still higher if all reports were reduced to the common denominator of the qualitative approach.

Two investigators report a total of 51 cases with 38 positive (or 75 per cent) when the dose was but 50 grams. Omitting the toxic pregnancy group where a superimposed physiological factor is patently operative, 17 in 58, or but 29 per cent, of our cases give a positive response.

The answer for these discrepancies is not far to seek. In a careful review of much of the lit-

TABLE VIII
LEVULOSE TOLERANCE

Positive Test Meal	I	Group II	III	IV	Total
Over 150 (%)	3	—	18	—	4
150 (%)	6	—	—	—	3
125 (%)	*6	5	*9	*8	6
100 (%)	14	*9	9	8	11
75 (%)	43	27	46	42	39
50 (%)	20	41	9	25	25
25 (%)	8	18	9	17	12

*Probable normal zone in box.

the augmenting thyroid influence, 18 per cent show high levels and 18 per cent normal, together they balance the 36 per cent who were normal with galactose. In the final sub-group (IV), there are no cases to parallel the report of increase with galactose, the normal fraction is the same and the depression is more frequent with the levulose than with its fellow.

Broadly speaking, there is a rough general parallelism in the indications with the two sugars, the levulose seems possibly less susceptible to the influences of superimposed endocrine states. But this type of statistical approach does not necessarily indicate the concordance or its lack with the individual components of the series. Warring any attempt at a nice quantitative reading and expressing each test as normal, increased, or diminished, the data can be subjected to a final analytical approach.

TABLE IX
CORRELATION OF SUGAR TESTS

Differ (%)	31	35	64	33	37

erature supplemented by a small group of personal observations, Freund⁶ has weighed the relative authority of the two sugars as indices of disturbed liver function. He finds no parallelism in his own results in the relative indications of the blood and the urine with levulose as the test meal. On the basis of all of the evidences, he concludes that levulose yields the more reliable indications when there is significant parenchymatous involvement, while galactose is the more dependable in cirrhotic conditions. Other states, such as jaundice from mechanical causes, syphilitic involvement of the liver and the like, yield results which are entirely indeterminate. In other words, the cases recorded in the literature, on which the quoted statistics are based, presented severe liver dysfunction, the majority of them with jaundice, and were not equatable with the greater portion of the patients in our own series with whom the liver derangement was functional in character and in larger measure unassociated with jaundice at the time of study. The differences recorded are of degree and not of kind, reflecting the severity of liver impairment. We feel that the approach through a series of graded test meals with the definition of that dose for each individual which will produce a transitory melituria, sharpens the significance of the test as an index of functional hepatic derangement. From the literature one would deduce that the differential diagnostic value of both sugars is most in evidence with the patients presenting obvious signs of severe hepatic involvement with jaundice, and even here the weighting rests on a relative and statistical basis. Failure to give due recognition to other factors certainly influencing carbohydrate metabolism is undoubtedly an element in the contradictory reports which comprise the clinical literature on this subject. The lack of uniformity in the conventions of the test and the criteria of positive response have already received comment.

In the series of studies of which this report is but one, we are endeavoring to ascertain, by a standardized technique and uniform approach, both the identity and character of the factors influencing the metabolism of this sugar and if possible, to give them quantitative significance. The work must be confined to man—the contradictory findings of Sachs²² and of Bauer² are but one illustration of the many forming the basis of this decision. That the mechanism of utilization of galactose and of levulose is not identical, seems to us a warrantable deduction from this and the other studies recorded in the literature. The use of adjuvants such as brandy³ or beef extract¹⁴ to sensitize and sharpen the test, has but little to recommend it, the problem is sufficiently complex without the addition of further extraneous factors. Such procedures and those in which more than one sugar is used may enhance the differential meaning of the

test but certainly do not clarify the underlying mechanisms of utilization. In the present study the only warrantable inference is that hepatic dysfunction tends to influence the utilization power for both sugars with qualitative agreement in two-thirds of the patients studied and with an equal lack of concordance in the remainder. Further, with both sugars a few subjects show an enhanced tolerance where the agencies usually producing this result are not demonstrably operative. Finally, galactose seems to be a slightly more sensitive index than levulose in this series of liver cases, the difference is, however, inconsiderable.

PATHOLOGICAL DISLOCATIONS OF THE SHOULDER BACKWARD AND ROTATION DEFORMITY

BY FREDERIC JAY COTTON, M.D.,* AND GORDON, MACKAY MORRISON, M.D.*

IN the main these are results of obstetrical paralysis, complicated often with residual muscle pareses, and with the queer bony overgrowths of which the down-hooked overgrown olecranon is the familiar type

One has learned to free the hindrance of tight pectorals, and J. W. Sever has very well taught us about clearance of the distorted overhang of the acromion

In occasional cases, however we are confronted with a persistent back-slip of the head, and in not a few with an inward rotation of the humerus and of the whole arm not anatomic but physiologic, conditioned probably on long shortened tissues and loose posterior capsule

For cases of each of these classes we have to-day a remedy worth noting

As to the backward luxation Nicola has

The Nicola operation

- 1 Biceps tendon (of long head)
- 2 Biceps tendon emerging from the artificial tunnel into the bicipital groove
- 3 Cut ends of biceps tendon sutured
- 4 Acromion

shown us the way, and I think Roberts' modification of his operation is serviceable. Both, and either, are efficient. Here there is no question of absolute anatomic repair. Nicola's operation is not a "restitutio ad integrum", nor need it be. What we want is an efficient mooring, better than the slinging to the acromion with fascia or tendon. The Nicola operation gives this absolutely. The biceps tendon run-

ning in its new course from the glenoid edge through the edge of the head to a fixed point in the bicipital groove gives an absolute and permanent fixation against backward displacement

In the other cases, which are rare, in which some congenital defect of muscle balance gives forward luxation or subluxation of the head, we gain by this operation a real and effective mooring

In the other class, those cases of obstetrical paralysis in which nearly complete muscle regeneration has been achieved, but in which the elbow comes up first with the hand lagging, there is an operation not new, but not familiar enough, that works

Disregarding all questions of anatomy, for it is *physiology* that concerns us, we may achieve correction by an osteotomy of the shaft just at or below the pectoral insertion an osteotomy with rotation outward of the arm, below the cut through something like 60°

Temporary fixation with a plate is desirable—otherwise contact of rotated fragments is hard to hold. The results are a bit amazing

Brief data of four cases follow. R. M., female, aged 27, nurse. Congenital shoulder. Seen September 15, 1931. Left arm showed a clean-cut picture of a brachial palsy of the Erb type. No actual paralyses remained, but she was much handicapped. On raising the arm forward it came up elbow first (internal rotation) and there was a very obvious posterior movement of the head of the humerus back to the back edge of the acromion (posterior subluxation). Motion was limited to a point below the horizontal plane.

On the arm being dropped the displacement reduced itself; there was some inward rotation due to a tight pectoral and the acromion was prominent, seemingly hook-shaped.

Shiagraphs showed a heavy hooked prominence downward of the end of the acromion, nothing else save general slight lack of bone growth.

Operation proposed and done. Anterior incision as usual. Acromion chiselled across, turned up. Part of pectoral insertion above was divided. A

typical Nicola operation was done, the divided biceps tendon pulled back up into the joint, brought down again through a tunnel and carried through the front part of the head to the floor of the bicipital groove. The cut ends of the biceps were then firmly sutured together.

Normal recovery was followed by greatly improved (not normal) range of motion forward, outward, and in outward rotation, and was very gratifying. After about 18 months there was an unfortunate recurrence of overgrowth of bone at the front of the acromion, which will need attention. There is and has been no trace of recurrence of the backward displacement.

E. O., female, aged 21, seen April 29, 1933, in consultation with Drs. Russell Sullivan and John Kerrigan. Chronic dislocation of both shoulders anteriorly. This shows a subcoracoid luxation on both sides. The history is curious and not clear. A healthy active girl, rather overplump, always had something queer about the shape of her shoulders but was never concerned about the lack of motion or use. About a month ago, as a result of an electric shock, the right shoulder was dislocated. It was reduced by Doctor Kerrigan. Shortly after, something happened to the left. I rather question the accuracy of her observation. At all events both shoulders were out and irreducible, showing in the x-ray small bones and some thinning of texture. Both heads were subcoracoid, the right more displaced than the left.

Operation on the right side, at Choate Hospital with Dr. Russell Sullivan, May 5, 1933. Hueter incision. Half of pectoral insertion divided. Incision up the biceps groove and in front of the capsule. The tendon was cut, and the proximal portion pulled into the joint. The soft parts were stripped from the edges of the small glenoid, but not easily. The dislocation was reduced and motion assured by stretching. A tunnel from the biceps groove through a point on the front edge of the articular surface of the head was made through which the biceps tendon end was passed from above downward, and both proximal and distal ends solidly sutured together, and to the edges of the bicipital groove. In suturing the capsule, the subscapularis, which was apparently normal, was advanced half an inch.

Second operation. The left shoulder was operated on at the Choate Hospital with Dr. Sullivan, June 20, 1933. The usual anterior incision the

head was forward but not so far out as the other had been. The same difficulty in tearing loose of evidently very old adhesions—from the edges of the small glenoid (particularly behind) in order to make reduction possible, was encountered. Then a typical Burrell-Cotton operation was done.

September 27, 1933. The left shoulder shows nearly normal range of motion. The right still shows limitation of near a half in abduction and external rotation. This was more of an operation than was needed on the right. Both are perfectly useful; neither has shown the least displacement of the head.

C. B., female, aged 30, seen June 13, 1931. Since earliest recollection she has had a partly crippled right arm and has had muscle training. This was an obvious obstetrical paralysis, with good return of muscles but with sharp internal rotation of the arm. For example, she cannot use the hand in eating. As always it is hard in this case to evaluate muscle imbalance, muscle spasm and possible skeletal change. The skiagraph showed marked lack of bony development of both glenoid and humeral head. Nothing else. Disregarding all this osteotomy was advised and done June 22, 1931, at the Faulkner Hospital (Cotton and Morrison). Anterior incision, osteotomy at the pectoral insertion and a four-screw bone plate was used. During convalescence an accidental trauma gave a lifting out of the bone screws from the upper fragment with a bit of outward bowing and excessive callus. The plate was removed August 22, 1931. Despite mischance, the end result is excellent with restored outward rotation and forward lifting motion.

M. McC., female. Age when first seen 13 years. (Boston City Hospital). This was an obstetrical paralysis in a particularly vigorous little girl in whom judicious exercise had brought back practically normal muscle action. There was unfortunately, about 50 degrees of internal rotation apparently not all from muscle contracture or contraction. At all events a cross section of the humerus was made through the insertion of the pectoralis major and the arm rotated out and held in traction in a Murray Jones splint. On July 22, 1932, eight years later, opportunity came to reexamine her. She had fortunately been a swimmer and had limbered and developed the shoulder wonderfully. To-day she shows full free motion, nothing objective save a negligible scar.

MEDICAL PROGRESS

ADVANCES IN PEDIATRICS*

BY R. CANNON ELEY, M.D.†

INFLUENZAL MENINGITIS

THIS type of meningitis is looked upon with a great deal of apprehension, as extremely few cases recover. Rivers¹ in a review of 220 cases in 1922 found a mortality rate of 92 per cent and subsequent reviews with the inclusion of additional cases have shown only fractional changes in this figure. Bloom² in a very extensive review of the literature both in this

country and abroad was able to collect twenty-four cases with recovery out of 302 cases. Jenks and Radbill³ recently reported thirty-two cases treated at the Children's Hospital at Philadelphia over a period from 1921 to 1929 inclusive with no recoveries. Gibbens⁴ in 1931 reported two cases with one recovery.

Ward, Fothergill and Wright^{5, 6, 7, 8, 9} in a series of recent papers have made an intensive study of influenzal meningitis from the point of view of producing a therapeutic antiserum, and the study of the mechanism of the action of such a serum. They confirmed the work of early

*From the Department of Pediatrics, Harvard Medical School and the Infants and Children's Hospitals, Boston.

†Eley R. Cannon—Associate Physician, Infants Hospital and Children's Hospital. For record and address of author see This Week's Issue, page 1134.

investigators showing the relative homogeneity of influenza bacilli. In addition they have shown that virulent meningeal strains are "smooth" in colony form and produce a specific soluble substance. These latter observations were also made by Pittman¹⁰

The above authors have also observed that the presence of agglutinins in the antiserum did not necessarily connote bactericidal activity. Precipitins in the antiserum, however, accurately parallel the bactericidins. In other words, in order to destroy the meningeal strains of influenza bacilli an antiserum must be capable of precipitating the specific soluble substance of virulent strains. The authors succeeded in producing such a serum in horses by prolonged immunization with formalinized virulent influenza bacilli.

In addition they have pointed out that complement is necessary for the bactericidal action of a serum possessing the above-mentioned properties. Complement is practically always absent in the spinal fluid of patients with influenza meningitis. Their treatment consists in the administration of antiserum plus fresh normal human serum as complement.

Therapeutic results so far have been encouraging. However there appears to be early "walling off" in this disease and in many cases, even though it was possible to sterilize the spinal fluid, yet the patients would eventually die from localized lesions. In a personal communication from one of the authors (Fothergill) it has been learned that they have had ten complete cures to date. Because of early "walling off" it is needless to emphasize the necessity for early diagnosis.

These investigators have pointed out also certain important statistical data regarding the disease. It is primarily a disease of infancy, about 80 per cent of the cases occurring during the first two years of life. Furthermore, the disease is much more common than is generally supposed, for in their review of meningitis in the Infants' Hospital of Boston they found it the third most common type during the first two years of life. Tuberculous meningitis is the most frequent type with meningococcus meningitis second.

Recently Fothergill and Wright⁹ have studied the possible reasons for the striking age incidence of influenza meningitis, and have found the incidence to be accurately correlated with the bactericidal activity of whole blood from individuals of various age groups. Cord blood and blood during the first six weeks of life possess considerable bactericidal activity for virulent strains. This probably represents a passively acquired humoral antibody transferred from the mother through the placenta and is gradually lost during the first two months

of life. It is interesting that the disease practically never occurs during the first two months of life. From two months to three years, the blood has practically no bactericidal activity and it is during this period that the majority of cases occur. From three years on, the killing power gradually rises. This killing power is probably due to an actively acquired immunity represented by a humoral antibody. This antibody, or its absence, is presumably important during the bacteremic stage of the disease.

TUBERCULOUS MENINGITIS

In 1932 Bokay¹¹ reported successful results in the treatment of five of seventeen cases of tuberculous meningitis (the diagnosis was established by both clinical and bacteriologic examinations) by energetic deep roentgen therapy. The author divided the cases into two classes, an exudative diffuse, and incurable group, and a local meningeal tuberculosis, it is this latter group that has responded to treatment. Wiener¹², encouraged by the report of Bokay, treated nine cases with roentgen therapy but was unable to obtain any improvement. In fact, it was his impression that the treatment hastened the death of the patients. However, some consideration must be given the fact that Wiener's cases were advanced while Bokay's were treated early in the course of their disease. Gordon¹³ treated three cases by this method with the following results: "Two of them, according to the concepts presented, offered no favorable response to this method, in that the tuberculous infection of the meninges was only an accompanying part of a generalized miliary dissemination of the disease throughout the body. The third patient was judged favorable for this form of treatment in that the infection of the meninges was the outstanding manifestation. All three patients died, the first two rather promptly. The third one, the child being favorable for treatment, showed a well-marked clinical response early in treatment, with decreased fever, improvement of physical signs, and most important, improvement of the sensorium and general clinical appearance. A relapse occurred after six days with death on the eighth day." The extremely high mortality rate of this disease certainly justifies any therapeutic procedure which, in itself, is free from danger to the patient. Obviously further clinical investigation is not only warranted but indicated.

POLIOMYELITIS

In view of both the favorable and unfavorable discussion concerning the efficacy of convalescent serum in the treatment of acute paralytic poliomyelitis, a brief review of this phase of the subject seems pertinent at this time of

the year "The initial symptoms are much the same in all types of the disease and they may be quite as severe in the nonparalytic as in the paralytic." This statement by Neal¹⁴ shows very clearly how difficult it is to determine the efficacy of any form of therapy instituted during the preparalytic period of acute poliomyelitis. Furthermore, it is impossible to evaluate properly the results of a given form of treatment unless the results can be compared with properly selected and supervised cases that did not receive treatment. The great difficulty in determining the value of convalescent serum (technic of obtaining and preparing serum¹⁵) has been the lack of control cases.

Soon after the introduction of this procedure in the treatment of acute preparalytic poliomyelitis, the literature contained favorable reports¹⁶ and one received the impression that convalescent serum was of definite value. However, the only controls were those cases diagnosed after paralysis had appeared and these patients, in many instances, were not seen prior to that time. Obviously, herein lay an actual error in drawing conclusions, for the number of patients who recovered *without* paralysis and who were never seen, could not be included. In fact, the only conclusion that actually could be drawn from these early observations was that *if the serum is of value, it should be given early*¹⁷ and before paralysis has developed. This same criticism, i. e., inadequate control groups, may be applied to the observations of recent authors^{18, 19, 20, 21, 22, 23} who advocate the administration of convalescent serum. Andrews²⁴ has presented evidence to show that when a virus of the filtrable class has made its biologic union with the tissue cells it is no longer within reach of a neutralizing virus. This observation offers a possible explanation for the failure of the serum to be of value as a therapeutic agent.

Torian and Winters²⁵ are of the impression that convalescent serum is of little value in influencing the course of the disease, yet they treated only four cases during the preparalytic stage. Definite conclusions cannot be reached from such a small number of cases. In an extensive series of 927 preparalytic cases, 519 of which were treated with convalescent serum while the remaining 408 were not given serum, Park²⁶ found that paralysis developed in 19.6 per cent of the treated cases, in only 1.1 per cent of the untreated cases, and that the mortality rate among the former group was 3.8 per cent as compared with 0.9 per cent among the latter group. The recent observations of Kramer, Aycock, Solomon and Thenebe²⁷ in a carefully controlled series of treated and untreated cases also fail to give any statistical evidence of its value as a therapeutic agent.

In her conclusion on the treatment of poliomyelitis by convalescent serum Neal²⁸ states "A group of more than 1000 cases, including

those of Kramer and Aycock, diagnosed in the preparalytic stage, with approximately half treated by convalescent serum, shows nothing to indicate the therapeutic value of the serum, either in reducing case fatality or in preventing paralysis. Indeed, the slight difference between the treated and untreated groups is against the use of serum. Since the same results were shown by three groups of workers, the physicians of the Health Department and Hospitals, the physicians working under the direction of the subcommittee on Poliomyelitis of the Public Health Relations Committee of the New York Academy of Medicine, and Kramer and Aycock and their associates—it may be concluded that these cases were diagnosed and treated without personal bias. It is fair to say, however, that there is a belief that the percentage of moderately severe cases was a little greater in the treated children in the group studied under the direction of the Academy of Medicine." At the present time, further observations among carefully controlled cases would seem to be indicated before definite conclusions as to the specificity of action in preventing paralysis in this disease can be drawn.

Convalescent serum has been administered intrathecally, intravenously, and intramuscularly, either alone or in combination with one or more of the other methods. The intrathecal injection of the serum, though advocated by some, does not appear advisable, for it is invariably followed by an exaggeration of the clinical manifestations of meningeal irritation. Furthermore, it is a well-recognized fact that the presence of serum of any nature within the cerebrospinal fluid establishes a sterile meningitis and thereby possibly increases the already existing reaction. The intravenous route is preferable, for in this manner large amounts of the serum may be readily administered and rapidly distributed throughout the body. If convalescent serum cannot be obtained and it seems advantageous to administer this form of treatment, a blood transfusion may be employed. Certain authors²⁹ have advocated this procedure over serotherapy, as a donor can usually be obtained without delay and larger amounts can be given.

The administration of convalescent serum, or whole blood, as a widespread prophylactic procedure has been advocated, but at the present time the scientific evidence is insufficient to warrant its acceptance as a universal measure. In view of the fact that the majority of adults have acquired an immunity^{30, 31} to the disease whereas young children have not, it may be advisable to administer serum intramuscularly or intravenously to this group when a member of the family has developed the disease. This passive immunity, however, is only temporary, lasting from five to seven weeks, and should the person be reexposed after this period, a second injection of serum would have to be given. If such prophylactic measures were employed,

many children would unnecessarily be subjected to treatment simply because a case, or suspected case, occurred in their neighborhood

NARCOLEPSY

In view of the increasing number of case reports in the literature and inasmuch as successful symptomatic treatment has recently been described by several writers, a brief review of this condition is of interest

Narcolepsy, first described by Gelineau²² in 1880, may be said to be characterized by two chief symptoms i.e., an irresistible desire to sleep, and a feeling of generalized weakness following laughing or other emotional disturbance. The desire to sleep may occur at any time, regardless of the attending circumstances and is unrelated to the amount of nocturnal rest, the patient may suddenly go to sleep while reading, eating, talking walking or working. This sleep resembles the "normal" sleep of an individual, although it may at times be accompanied by hallucinatory dreams which in themselves may cause the patient to awaken. As has been pointed out by Adie²³ there are occasions, however, when the weakness or cataplexy may result in closure of the eyes and inability to articulate, thereby giving the impression of sleep. The attacks of generalized weakness, or the cataplectic attacks, are precipitated by emotional disturbances, the most common of which is laughter. In fact many of these patients refuse to laugh, knowing well that any such act will be immediately followed by a generalized sensation of weakness which may result in their collapse, less frequently fear, anger, or distress may produce this same sensation.

The etiology of this condition continues to be obscure, although there is good reason to believe that in certain cases it may be symptomatic, i.e., secondary to trauma, disturbances in glandular functions, infection etc. Due to the fact that an increased number of these patients have been seen since 1918 (the year of the epidemics of influenza and encephalitis) it has been suggested that there might be a relationship between epidemic encephalitis and narcolepsy. Wilson²⁴, however, in his excellent review of the subject in 1928 makes the following statement "Were one to argue from these considerations, a case might be made out for an actual increase in disordered conditions of sleep somehow related to the times in which we are living, and their ascription to processes out of epidemic encephalitis might be plausibly offered as one of explanation, but at present I am far indeed from being convinced of any frequent etiological association of the latter with the former." In regard to other etiological factors he states "The data which have just been examined are sufficient to show how diverse and heterogeneous is the etiology of the narcoleptic syndrome. To assert the causal fac-

tors is a matter of no little difficulty, a provisional arrangement might be made along the following lines

- 1 Traumatic group
- 2 Psychopathological group
- 3 Endocrine group
- 4 Epileptic group
- 5 Toxic-infective group (epidemic encephalitis, etc.)
- 6 Circulatory group
- 7 Pressure group (cerebral tumors, etc.)
- 8 Group in which no Grundkrankheit has been discovered"

Thrash²⁵, Spiller²⁶ Weech²⁷ and others have reported cases in which there appeared to be a definite relationship between endocrine dysfunction encephalitis and trauma and this disturbance

The age incidence is such that narcolepsy is more frequently encountered in adults than in children. Cave²⁸ in a report of 42 cases found that the age of onset varied from nine to forty-six years with an average of twenty-five years in males and from eight to thirty-seven years in females, with an average of nineteen years. Levin²⁹, in a study of the published cases, found only 4 in which the age incidence was under ten years. In Cave's cases 34 were males and only 4 females, in Wilson's there were 37 males and 7 females, while in Adie's group of 20 (17 from the literature and 3 of his own) there were only 3 cases in females. Judging from the increased number of case reports of this condition in children during recent years one may later find that the disease is not so rare in this age group as the present statistics would lead us to believe.

The diagnosis can usually be established without difficulty if both symptoms are present. If the chief complaint is that of recurrent or frequent attacks of sleeping, there is reason for possible confusion before the proper diagnosis can be established. In some cases the cataplectic attacks may occur alone or for several months before the sleeping attacks appear, and it is in this group that one might be misled by considering epilepsy or petit mal. However, careful questioning will reveal the fact that the attacks of weakness occur only after *emotional* disturbances (especially laughing), are not accompanied by loss of consciousness (for these patients can be readily awakened), or by loss of sphincter control, and that they are not followed by stupor or prolonged periods of unnatural sleep.

The treatment of narcolepsy like all idiopathic disturbances has passed through many forms and processes and the result has always been the same. However in 1931 Doyle and Daniels³⁰ reported successful symptomatic treatment by the oral administration of ephedrin sulphate. Quoting their summary "Six pa-

tients suffering from narcolepsy were treated with ephedrin sulphate. Five were completely relieved of the essential symptoms of irresistible desire to sleep without apparent cause and cataplexy. The sixth patient is relieved of cataplexy and hypnagogic hallucinations, and somnolent tendencies are markedly improved. Similar results have subsequently been reported by Wahl⁴¹, Collins⁴², and Jacobsen⁴³. The usual dose has been 3/8 of a grain, three times a day, although at times it has been necessary to increase this to 3/4 of a grain three times a day before satisfactory results could be obtained. Daniels⁴⁴ recent monograph, with a detailed study of 377 cases, will prove of inestimable value to those interested in this subject.

PLACENTAL EXTRACT

One of the most outstanding advances in pediatrics has been the introduction and employment of human placental extract in both the control and modification of measles. McKhann and Chu^{45, 46}, in their original publications, demonstrated that placental protein extracts contained substances, presumably antibodies, which (1) neutralized diphtheria toxin, (2) blanch scarlet fever rashes, (3) neutralized poliomyelitis virus, and (4) prevented measles in exposed susceptible patients. At present the most extensive investigations in the use of this material have been in the prophylactic treatment of measles. Up to the present time it has been used in over seven hundred individuals⁴⁷ either for prevention or modification of the disease. In ninety-five non-immune patients exposed to measles in the course of hospitalization for other causes, the extract was administered early in the period of incubation in order to prevent the disease, and of this group ninety-one did not develop the disease while the remaining four developed very mild modified measles⁴⁸.

Among the factors which influence the effectiveness of the extract in the prophylaxis or modification of measles are (1) time of injection, (2) dosage and (3) potency of the material. By pooling human placentae in large lots to minimize the variation in antibody content of individual placentas, and by standardizing the dosage of the preparation on the basis of its protein content it has been possible to prepare an extract of almost uniform potency which promises to eliminate variability in results. For prevention of the disease a dosage of 5 cc given within four days after exposure has been found to be effective whereas the same dosage given from the fourth to the ninth day after exposure has modified the disease. In certain instances large doses given after the appearance of Koplik's spots have altered the usual clinical course. Local reactions have occurred

in about ten per cent of the treated patients and have been characterized by pain, tenderness and redness. At times this local reaction may be accompanied by malaise, headache, and a slight febrile reaction, all of which, however, usually subside within 24 to 36 hours. Although serum reactions have occurred in only two out of several hundred treated patients, yet this is sufficient to indicate that adrenalin should always be available whenever the extract is administered.

THE BACILLUS CALMETTE-GUERIN (BCG)

Recent developments concerning the inoculation of children against tuberculosis with the BCG vaccine may be considered under two general headings.

(1) The safety of the method. This question has been attacked, mainly by animal experimentation, to determine whether the organism preserved a fixed (and harmless) virulence under varying conditions. Petroff⁴⁹ has dissociated the bacillus on a gentian-violet egg medium into a predominant R and a rather infrequent S strain, which was pathogenic for animals. Sasano and Medlar⁵⁰ report a dissociation on culture on another medium, with a resultant strain definitely pathogenic for rabbits, guinea pigs, and calves. Feldman⁵¹ has reported some evidence of pathogenicity of the bacillus for guinea pigs, but this was not heightened by subculture or animal passage. Dreyer and Vollum⁵² have stated that the virulence of BCG vaccine could be enhanced by culturing in partial anaerobiosis.

On the other hand, there have been several reports by investigators who have failed to confirm the above findings, and who feel that BCG vaccine is non-pathogenic, at least for laboratory animals. Park and his co-workers⁵³ have repeated the procedures of Petroff, Sasano and Medlar, and Dreyer and Vollum, without any evidence of increased virulence. In three animals out of about 350 inoculated in these experiments a progressive tuberculosis developed, which the authors believed was due to cross infection. Birkhaug⁵⁴ has repeated Petroff's and Dreyer and Vollum's work, without confirmation of their results. Griffith⁵⁵ reports a complete lack of virulence of the organism in guinea pigs, goats, and fowls, and a pneumonic disease in rabbits only after the intravenous injection of large doses.

(2) The production of immunity. It is interesting to note that although approximately a million children have received BCG vaccine yet there is no absolute proof or disproof of its value. The French statistics have not been adequately controlled⁴⁹, in England the method has failed to gain any sanction⁵⁶, and in Germany little inoculation has been reported since the

disaster at Lubeck in 1930 (The official investigation has decided that the deaths of vaccinated children at Lubeck were due to contamination or substitution of the culture used, rather than to change in virulence⁵⁷, although others who have also studied this matter have different views⁴⁹) Perhaps the most valuable studies of the protective value of the vaccine in children are those of Wallgren⁵⁸ in Gothenburg, and of Park and his associates⁵³ in New York. In both of these investigations the best use of the BCG vaccine has been thought to be its intracutaneous administration to young infants in tuberculous families. Wallgren's report includes 194 children and Park's includes 150 children vaccinated in this manner. No deaths have occurred from tuberculosis in either group, while tuberculous mortality in suitable controls was about 3 per cent in each series. The protective value of BCG vaccine inoculation in animals has been repeatedly demonstrated, for a careful study the reader is referred to the work of Birkhaug⁵⁴.

It is possible, in a review of this kind, to mention only a very small portion of the literature on the general subject of the BCG vaccine. It is evident that large and extremely painstaking statistical studies, such as are developing in New York, will be necessary before definite proof of the advantages of BCG vaccination in children is obtainable.

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL PATHOLOGIC EXERCISES

EDITED BY RICHARD C. CABOT, M.D.

F. M. PAINTER, A.B., ASSISTANT EDITOR

CASES 20221 AND 20222

DR. TRACY B. MALLORY These next two cases are so similar that I am going to ask that both histories be read first and followed by a general discussion of both cases.

PRESENTATION OF CASE 20221

First admission A white boy four and a half years of age was referred from another hospital. The complaints were sore throat and rapid heart.

Family history His mother and father were well but were not living together. One sister two years of age was well. The second pregnancy resulted in a miscarriage at four months. No family history was obtained of allergic manifestations, tuberculosis, lues, insanity, kidney or heart disease in any form.

Past history The patient was delivered normally at full term and was active and vigorous. He was breast fed for nine months. Cod liver oil and orange juice were started at three months, vegetables and cereals at six months. His development was normal. He had possible measles at three months, with rash, conjunctivitis and bronchitis, chicken pox at three and a half years, and scarlet fever at four years, with no sequelae noted. He had never had chorea or joint trouble, but did have frequent sore throats and colds.

Present illness Two and a half years before admission, at two years of age, he had his first attack of tachycardia. His mother found him lying on the ground in the yard, but not unconscious. He complained of pain over the heart. Although he did not appear to be very ill, he was put to bed. Shortly afterward he began to vomit. For about twelve hours he wished to be let alone, and lay quietly. Then the attack passed off. Attacks like this recurred about once a month. One attack with severe vomiting for three days culminated in unconsciousness, and he was taken to a hospital. Since that time he had had eleven admissions for the same cause. His mother felt that his attacks increased in frequency following a fright, and she believed that fear brought them on. They were however preceded by a severe tonsillitis. They lasted from twenty minutes to two weeks. During the six weeks he was in bed with scarlet fever some six months before admission he had no attacks.

Lately attacks had occurred as often as once a week, but were less severe. The boy could usually tell when an attack was coming on. He became fretful and very irritable. During this time his pulse would not be rapid. He might go to bed voluntarily before the actual onset of the attack. During the attacks he vomited and refused all food. His tongue became coated. The stools were normal in number but showed undigested food. If the attacks lasted several days his skin became blotchy, there was circumoral pallor and later general pallor. If the attacks lasted a week his ankles, hands and face began to swell. Medication had not affected the attacks.

Physical examination showed a well developed and nourished, somewhat pale, cooperative boy. His tonsils were moderately injected and cryptic, and there were yellowish spots on the pharynx and tonsils. There was moderate cervical adenopathy. The heart rate was 90, the respiration 24, and the temperature 101°. The blood pressure was 92/52. The left border of dullness was 6.5 centimeters from the mid sternal line, almost a centimeter beyond the midclavicular line. There was a soft systolic murmur heard loudest in the fifth interspace, also heard at the apex and in the pulmonary area. There was an occasional extrasystole, and a questionable third sound along the sternal border at the fourth left interspace.

Laboratory work The examination of the urine was negative. Tuberculin and Hinton tests were negative. The stools were negative. Examination of the blood showed a red cell count of 4,300,000 with a hemoglobin of 65 per cent and a white cell count ranging between 17,000 and 35,000, with 70 per cent polymorphonuclears.

An electrocardiogram on admission showed sinus arrhythmia, rate 50 to 70, prominent P₁ and P₂, left axis deviation, and slightly slurred and widened QRS. During an attack an electrocardiogram showed paroxysmal auricular tachycardia, rate 280.

Course The child had several attacks of paroxysmal tachycardia lasting four to eight days, the rate going as high as 280 per minute. The attacks were as described in the history. The apical rate during the attacks ranged between 200 and 280, with a radial pulse of 100 to 150. Between the attacks the rhythm was often quite irregular, with a rate as low as 60 associated with coupled beats. Acetylcholine was given during one attack without definite effect. Injection of the left dorsal sympathetic ganglia with novocain did not affect the tachycardia. Injection of the right dorsal ganglia with novocain stopped the paroxysm immediately. On two subsequent occasions a paroxysm was stopped by injection of novocain. In order that the effect might be more permanent, on the last occasion after the novocain was injected alcohol was injected into the ganglia, no further paroxysm occurred during

ing the four days he remained in the hospital. At the end of five and a half weeks the child was discharged.

History of interval He was well until two weeks after his discharge, when an attack started which lasted until half past three p m on the fourteenth day after its onset, at which time the heart resumed its normal rhythm. Later in the day, after he had begun to vomit again and his pulse rate had increased, he was brought into the hospital.

Second admission, a month after his previous discharge.

He was pale and in some distress. He had definitely enlarged cervical glands. The heart was not enlarged, no murmurs were heard, the rate was 220. The liver was not tender, but was two and a half fingerbreadths below the costal margin. The blood pressure was 120/80. Physical examination was otherwise negative. The laboratory findings were negative except for a white blood cell count of 25,400.

Course The pulse remained high. The liver increased slightly in size. There was no edema. On the fifth day in the hospital the right inferior cervical and upper dorsal ganglia were injected with novocain. Within one hour the heart rate dropped from 240 to 100 beats per minute. On the following day the child was brighter and much more active. His color was good. The liver was only one and a half fingerbreadths below the costal margin. The pulse was slow and regular.

At four o'clock in the morning of the second day following the injection, the child sat up in bed and screamed with pain. He then became semicomatose. His pulse rate increased. Response was difficult to obtain. At eight o'clock, although acutely ill, he could understand questions. Both pupils reacted to light and were equal in size. There was a drooping of the left eyelid and left facial paralysis. The tongue deviated to the left and a left hemiplegia was present. The right arm and hand were dry and cold and the left arm warm and moist. At ten a m the pulse was 100. There were nystagmoid motions of the eyes and twitching of parts of the body. The abdomen became distended. The child died at half past nine p m after expelling mucus and blood tinged froth from his mouth.

PRESENTATION OF CASE 20222

A twenty months old white native born male infant entered the hospital with the complaint of cough and occasional vomiting since an attack of pertussis two months earlier.

The previous summer a doctor had said he was anemic, but he seemed otherwise well until August when he had whooping cough. After three weeks this progressed into pneumonia and he

spent the next month in a hospital for contagious diseases. Upon returning home from that hospital he still had some cough, mostly at night, and some of the attacks were followed by vomiting. There was no temperature. During the three weeks before admission he had been restless, irritable and fretful and his appetite had been poor.

The past history showed a full term normal delivery. The weight was eight pounds, and he was considered normal in every way at birth. From the first he received a formula of condensed milk and water, with no cod liver oil or orange juice. At entry he was still being fed on a formula with vegetables and egg yolk. He sat up at four months, but had not yet walked at twenty months. His general development had been slow. He was very sick with bronchopneumonia at nine months of age.

The mother and father were aged nineteen and twenty-two respectively, and were in good health. One sibling died at six months with whooping cough. The family history was otherwise negative.

Physical examination showed a pale, chubby, washed-out looking infant not acutely ill. There were signs of rickets in prominent frontal bosses and a rosary. There was some mucoid discharge from the nose. The throat was reddened and there were small shotty glands palpable over the neck. A few scattered musical râles were heard over the chest. The heart was enlarged somewhat to the left of the midclavicular line. The rate was 160 and regular. No murmurs were heard. The abdomen was a "pot belly" with a prominent umbilical hernia. The liver edge was palpable at the level of the iliac crest.

The temperature was 101°. The respirations were 30.

Laboratory work The blood showed a red cell count of 5,800,000, a white cell count of 25,100 and 72 per cent hemoglobin. The blood smear showed a normal differential count, with marked polychromatophilia and anisocytosis of the red cells. Hinton and tuberculin tests were negative.

X-ray examination of the chest showed the hilus shadows prominent on both sides, pleural thickening on both sides, and a prominent bulge in the region of the right auricle.

An electrocardiogram showed paroxysmal tachycardia with a rate of 200.

For the first two days the pulse varied between 110 and 180. On two occasions during the first ten days in the hospital Dr J C White injected the first and second right thoracic sympathetic ganglia and on one occasion the left with novocain, producing a slight Horner's syndrome but no appreciable effect on the pulse. Following this the child was digitalized in an endeavor to slow the pulse, but there was no

slowing of the rate, although the child's general condition was better. Digitalis was then discontinued, and a tincture of veratrin, one minim three times daily, was begun. For a time the boy seemed to be doing well, the heart showing many dropped beats, but clinically he was not so well as he had been under digitalis. He was next given quinidine sulphate, the dose starting with two and a half grains daily and slowly increasing. He did not do well under this régime, and when the dosage reached fifteen grains daily he went into collapse, but recovered when stimulants were given. The quinidine was stopped. Acetyl cholin was tried once, with only slight physiological effect and no effect on the pulse. The patient was next digitalized and put on quinidine sulphate one half grain three times daily by rectum. On this régime the pulse steadily tended downward, and after five days the electrocardiogram showed a normal rhythm for the first time since he entered the hospital, with a rate of 140. After stopping digitalis and quinidine for forty-eight hours the normal rhythm became interrupted by many auricular beats, which disappeared upon restoring quinidine but omitting digitalis. Soon afterward he developed pneumonia and otitis media, but recovered. During the pneumonia his tachycardia returned, and resisted all attempts to restore normal rhythm with digitalis and quinidine. On recovery from the pneumonia, the child again showed improvement in general condition and at times a normal pulse rate (120 per minute). At other times the pulse varied up to 200. He developed pneumonia (left lower lobe) again five weeks after recovery from the previous infection. He was very ill, the pulse rose to between 200 and 220. The temperature then rose steadily to 107°, and he died three days after pulmonary signs appeared, five months after he entered the hospital.

X-RAY INTERPRETATION

DR AUBREY O HAMPTON This film was taken twenty-two days before death and thus one a month and a half. The total transverse measurement of the heart is 9.6 centimeters. The internal diameter of the chest is 17.8 centimeters. I think we cannot compare these two because in this case there was rotation. The diaphragm has come down after the second examination and there seems to be more passive congestion in the lung. The enlargement of the heart is diffuse, but seems to be more to the left in this film, and here we have a triangular shaped heart, but I think that is due to the position of the patient.

CLINICAL DISCUSSION

DR MALLORY I believe you saw these cases, Dr Eustis. Would you like to say a word?

DR RICHARD S EUSTIS I saw the second of the two cases at the end, after the child's first attack of pneumonia, while he was running apparently a paroxysmal tachycardia. We did not know what else to call it. We tried to control it with quinidine without much effect. Dr Boone knows the details of that far better than I do.

Clinically he was a cheerful child sitting up in bed smiling and sleeping most of the time, with a pulse rate of 200. I suspect that the pneumonia was a terminal complication and not the real cause of death, because his pulse rate started climbing before his temperature went up and signs of pneumonia appeared. I suspect that his heart began to go bad and he then developed a pneumonia and died of pneumonia.

I am completely at sea as to the underlying cause of such a condition. I have never seen anything like it before. I have heard of comparatively innocuous paroxysmal tachycardia in older children and young adults, but this picture is entirely novel to me. I hope Dr Mallory can tell us more about it.

DR JOSEPH GARLAND I saw only the second of these two children when he first came in. I think both the cases illustrate the difficulty encountered in controlling paroxysmal tachycardia.

DR HAROLD L HIGGINS I think in the second case the question of pertussis playing a rôle in the etiology comes up. I looked in many textbooks regarding pertussis, and I find no mention of pertussis affecting the heart at all, except that following severe paroxysms of coughing there is sometimes dilatation of the right ventricle. This child had pertussis and a bronchopneumonia which went with it and kept recurring, and no doubt this played some rôle in his cardiac condition.

As to the first case, the cause of death was pretty clearly cerebral embolus. This child showed a much more rapid tachycardia than the second child. He would show distinct signs of cardiac failure after his paroxysmal tachycardia had continued over a period of twenty-four hours. The second child seemed to stand the tachycardia quite well until he got an infection. When his bronchopneumonia became marked we found signs of cardiac failure.

DR PAUL D WHITE These are two rather extraordinary cases of course, not showing the usual results of paroxysmal tachycardia, a condition that is ordinarily considered to be unimportant, well limited in attacks and allowing many years of life. There are patients on record who have had paroxysms of tachycardia for thirty or forty years without causing any serious heart involvement and without any heart disease to start with. The chances of the presence of heart disease in a patient who has par-

oxysmal tachycardia are probably only one in three or four, perhaps less. Serious paroxysms are very uncommon. Here, however, we have two very young children who had fatal complications. There was no clear proof during their illness of organic heart disease, although there was some indication of cardiac enlargement in the second case and in the first child there was an abnormality of the electrocardiogram other than the paroxysmal tachycardia, when the rhythm returned to normal the electrocardiogram revealed abnormal QRS waves, which ordinarily indicate intraventricular block and lead us to think of myocardial disease. We have not found paroxysmal tachycardia, however indicative of congenital defects or in any of the rheumatic involvements of the heart with which we are ordinarily familiar.

I will pass around these records. The first set is a group of three electrocardiograms taken from the first child. The first record of the set was obtained during a paroxysm of tachycardia with a heart rate of 230 and some intraventricular block. The second and third records were taken during the injection of novocain and show either normal rhythm or an alternation of normal rhythm and short paroxysms of tachycardia; there is a persistence of the intraventricular block during the normal rhythm. The second set of records, from the second child, shows normal QRS waves with inverted P waves of auricular paroxysmal tachycardia; in the last strip of the first record you will note that there is one dropped beat, due to the production or occurrence of block. We were able by the use of digitalis to increase the degree of this block and therefore to reduce the heart rate. It is possible that, if there had not been pneumonia, digitalis and quinidine might eventually have controlled the situation. That of course remains in doubt.

The very fast heart rate during the paroxysms of tachycardia in these two children is rather characteristic of this disturbance of rhythm in extreme youth. The fastest rates that I know of were in two infants: one a case of Dr Paul Emerson with a rate of 310 and the other a recent case of Dr Lyons of Washington with a rate of 320, both proved electrocardiographically; the latter case so far as I know is the world's record. The fastest heart (ventricular) rate that we have recorded electrocardiographically in our laboratory at the Massachusetts General Hospital in an adult was 273; this case, a woman, recovered and lived for years after that record was obtained.

DR HOWARD B SPRAGUE. I had charge of the first case when the child was at the other hospital. We were impressed by the fact that change in position or emotional stimuli would produce or terminate the attacks. Standing him on his head would stop an attack. On the other hand falling out of bed might start one. It is

very difficult for me to see how such procedures alter the condition of the myocardium. One would suppose that the effect was produced through some nervous reflex.

The second case I saw also and at one time brought up with Dr James C White the question of cutting down upon and electrically stimulating the vagus nerves. I hope Dr White will tell us something about that procedure.

DR T DUCKETT JONES. The first case I saw over a period of two years at the two outside hospitals. During one attack they found the child had a blood sugar of fifty and gave him intravenous glucose and the paroxysm suddenly stopped. With subsequent attacks however the blood sugar was always normal, so the influence of hypoglycemia did not help. The emotional side in this case was very striking. One day I went into the ward and picked up a balloon that was lying on the table and the child became violently angry and started to have a paroxysm of tachycardia at about 200 a minute. I hope Dr White is going to have something illuminating to say on that. So far as I know everything was tried for a period of two years that possibly could have been tried. That is why he was sent down to Dr White.

DR JAMES C WHITE. Of course paroxysmal tachycardia is supposed to be an intrinsic disease of the pace regulating mechanism of the right auricle. It was a question whether doing anything to reduce the activity of the extrinsic cardiac nerves could control these attacks by diminishing the irritability of the sinoauricular node. There was some indication for that in this patient's history, as his attacks were often set off by emotional factors and also the fact that when he had a high fever his attacks stopped. A high fever we know diminishes certain forms of sympathetic activity. In order to test the effect of paralysis of the cardiac accelerator nerves I blocked the upper four thoracic sympathetic ganglia on the left side with novocain. This had no effect at all. When I tried it on the right side there was an immediate cessation of his tachycardia that you can see by looking at the electrocardiograms. It was successful twice.

I think the mistake we made with him was in not going on that evidence and resecting these ganglia rather than attempting an alcoholic injection with which I had had no experience in so small a child. If operation had been done there is a fairly good chance that he would not have developed any more paroxysmal tachycardia. Possibly if that had been done in the beginning he would not have shot off his final and fatal embolus. Dr Leriche in Strasbourg has operated on two of these cases. One has been followed for a period of a great many years with no recurrence of the tachycardia. I believe Dr Paul White thinks that the first case of angina pectoris that was operated on in 1916 by

Jonnesco was very probably paroxysmal tachycardia

In the second case novocain gave no evidence of benefit. Instead of cutting down and stimulating the vagus, as Dr Sprague suggested, he was given acetyl cholin, which is known to produce a very definite stimulation of vagal activity. This gave no benefit, and further neurosurgical investigation was discontinued.

CLINICAL DIAGNOSES, CASE 20221

Paroxysmal auricular tachycardia
Cerebral embolism
Pulmonary congestion
Left hemiplegia

ANATOMIO DIAGNOSES, CASE 20221

(Paroxysmal auricular tachycardia)
Cardiac hypertrophy
Mural thrombus, left ventricular wall
Cerebral embolism and infarction
Congenital bicuspid aortic valve
Endocarditis, chronic, tricuspid
Diffuse thickening of the endocardium
Chronic passive congestion of liver and spleen
Hydrothorax, bilateral.
Hydropericardium
Pulmonary congestion
Dilatation of stomach
Intussusception

CLINICAL DIAGNOSES, CASE 20222

Paroxysmal tachycardia
Lobar pneumonia, left lower

DR HAROLD L HIGGINS' DIAGNOSES, CASE 20222

Paroxysmal tachycardia
Bronchopneumonia, left lower

ANATOMIO DIAGNOSES, CASE 20222

(Paroxysmal auricular tachycardia)
Hypertrophy and dilatation of heart, especially right auricle
Bronchopneumonia, bilateral.
Petechial hemorrhages of mesentery, thymus, epicardium
Chronic fibrous pleuritis, left
Hydrothorax, left, slight

PATHOLOGIC DISCUSSION

DR MALLORY The autopsies on these two children showed nothing anatomical which might explain their tachycardia.

The older child, the first case, had an abnormal heart shown for one thing by a congenital bicuspid valve. There was absolutely no evidence of endocarditis of this valve and the microscopic anatomy fits perfectly the criteria of Lewis and Grant*. We found moreover in the apex of the left ventricle a rather loosely adherent antemortem thrombus. It was attached

at only one very minute spot to the ventricular wall and the ventricular musculature immediately under it was perfectly normal. I think there is no doubt that it was from this thrombus that the embolus broke off which lodged in one of his anterior cerebral arteries in the frontal lobe and was the immediate cause of death.

A point which immediately arrested our attention was the unusual thickness of the endocardium of the ventricles, particularly the left one. When a heart is opened at the autopsy table the endocardium of the ventricles is very translucent and one can easily see the pink musculature through it. The endocardium is normally of varying thickness in the individual chambers and in the left auricle is normally so opaque that it appears as a white layer through which we cannot see the musculature at all. In this child the endocardium throughout the heart was of the same thick white opaque character that you normally find in the left auricle. This was particularly striking in the left ventricle. Two minute fibrous tabs, presumably healed vegetations, were found on the tricuspid valve.

Microscopic sections show a few very minute areas of scarring and fibrosis within the myocardium. The endocardium shows collagenous and elastic thickening of extreme degree. I have never seen, except over an old area of infarction in an elderly man, so thick an endocardium as this boy shows. Otherwise the findings are entirely negative. It is possible to imagine that this thickened endocardium might have interfered in some way with conduction in the bundle. Heart block, however, was an inconspicuous feature of the case. The sinoauricular node is the only point where an anatomical lesion would explain the auricular tachycardia, and the node so far as we can make out is entirely negative.

In the second case there was a slight degree of thickening of the endocardium, although not nearly so marked as this, and numerous sections from all parts of the heart, including the sinoauricular node, fail to show any evidence of myocardial scarring or any acute myocardial process.

It seems to me that one must consider these cases as essentially functional heart disease and has to admit the possibility of death from functional disease. In living patients in the clinics we are always constantly aware of the frequency of functional disease, but on the autopsy table one ordinarily assumes that it can be ruled out. I do not believe that we are always justified in doing so, however. I feel quite sure that there are certain types of functional disease so severe that they can cause death, and I personally should be inclined to place these two cases in the group.

DR PAUL D WHITE May I add a word

*Lewis Thomas and Grant. Ronald T. Heart 10: 21, 1923.

about the first case? I should think that if there is that extensive abnormality of the endocardium it must also have involved the right auricle. There might thus be an organic basis for irritability of any part of the auricular myocardium which would render more likely the precipitation of paroxysmal tachycardia through nervous channels. It is conceivable that this abnormality of the endocardium might involve also the branches of the auriculoventricular bundle of His which lie just under and in contact with the endocardium, thus explaining the intraventricular block found in the electrocardio-

gram. We have seen such thickening of the endocardium in a few instances of congenital heart disease, particularly in two or three in which there was pulmonary stenosis or stenosis of the infundibulum of the right ventricle, which suggests that there might have been an intrauterine infection, that is, an endocardial infection during fetal life with or without involvement of the valves.

DR MALLORY: I think one is constantly meeting the problem as to which is art and which is horse. I do not think we can settle it in this case.

The Massachusetts Medical Society

THE WORCESTER MEETING

LAST June the Worcester District Medical Society cordially invited the Massachusetts Medical Society to hold its next annual meeting in Worcester. Often such an invitation is purely perfunctory, and those extending it feel that their responsibility ends with its acceptance. But the Fellows of the Worcester District feel keenly their position as hosts, and have done everything in their power to make the meeting a success. At their annual meeting on May 9, 1934 they unanimously voted to assume the expense of entertainment for the Fellows and their wives, and a very generous sum was set aside for that purpose.

The Local Committee of Arrangements has been most cooperative, and helpful to the State Committee, and has planned excellent clinics for Monday, June 4, at all the leading hospitals

of the city. After these clinics, luncheons will be served at the hospitals through the courtesy of the Worcester District Medical Society. The Local Committee has also arranged with the Worcester, Taunuck, and Wachusett Country Clubs to permit all Fellows and guests of the Massachusetts Medical Society to play golf as guests of the Worcester District Medical Society at any time during the three days of the meeting.

The Annual Meetings have always provided for the Fellows of the Massachusetts Medical Society an opportunity not only to refresh or make additions to their professional knowledge, but also to renew old friendships and make new ones. The value of the social aspect of these meetings should not be underestimated. In the past when entertainment has been provided for ladies, many Fellows have come with their wives, and the enjoyment of the meetings has been greatly enhanced.

Our hosts of this year have arranged an elaborate program of entertainment for visiting ladies, the details of which appear on page 1194 of this issue.

Women are taking an increasing interest in the activities of the medical profession. Should we not now consider the advisability of forming in Massachusetts a branch of the Woman's Auxiliary to the American Medical Association?

It is a pleasure for us to welcome the wives of Fellows at our meetings, and we feel that such contacts should give them a better understanding of their husbands' work.

"CANCER IS CURABLE"

THE bright side of the cancer subject needs to be occasionally repolished and presented anew. The results of all the work that is going steadily on merit a feeling of optimism, but there is enough that is disheartening to make us occasionally forget that progress is being made. It is well, therefore, that the *Cancer Clinic Bulletin* of the Massachusetts Department of Public Health should this month summarize the symposium conducted by the American College of Surgeons in October on the curability of cancer.

Six objectives were in view when this symposium was proposed.

1 To impress upon the practitioners of scientific medicine, and indirectly upon the public, the fact that carcinoma is curable by the use of well known and established methods of treatment.

2 To point out in a convincing manner that if all cases of cancer could be diagnosed early and treated promptly in their incipency, the annual death rate from the disease, now recorded as one hundred and fifty thousand in the

United States and Canada, would be reduced by at least thirty-three per cent, or fifty thousand per year

3 To bring together a group of distinguished clinicians to present definite statements of the impressive number of cases of cancer that have actually been cured

4 To secure the maximum of ethical publicity of the reports

5 To convince the profession and the public that even though cancer is already apparently in a later stage of its development, if it is subjected to proper treatment its progress may often be delayed and the disease not infrequently cured

6 To establish a universal policy among physicians and surgeons to report cancer cures rather than to present the involved comparative statistics that dwell particularly on the cases not cured

Reported cancer cures during the years 1932 and 1933 are forthwith summarized, the grand total of five year and over cures amounting to twenty-four thousand, four hundred and forty-eight. The percentage of cures, of course, varies in different localities and in different types of malignancy

Dr Malcolm B Clopton of St Louis reported one hundred and twenty-six breast cancers. Of thirty-seven cases with the disease in the breast alone, there were twenty-four, or sixty-four per cent living and well five years after operation. Of eighty-nine cases in which the cancer extended beyond the breast, twenty-seven, or thirty per cent were alive and well. Harrington and Judd, of Rochester, Minnesota, reported on a series of two thousand six hundred and fifty-six cases that twenty-six per cent of those with, and seventy-one per cent of those without involvement of lymph nodes had survived the orthodox five-year period. Greenough of Boston reported a total salvage of twenty per cent of cases operated on between the years 1894 and 1926. Other similarly encouraging reports were included

Of one hundred and fourteen cases with carcinoma of the cervix Anspach of Philadelphia reported 18.4 per cent cures, and Crossen of St. Louis twenty-four per cent. Healy of New York reported eighty-five per cent of five-year cures in cancer of the body of the uterus. Charles C Lund of Boston presented an analysis of the cases of carcinoma of the buccal cavity and lips treated at the Collis P Huntington Memorial Hospital from 1918 to 1926, reporting that of four hundred and thirty-two cases of carcinoma of the lip and one thousand one hundred and thirteen cases of carcinoma of the buccal mucosa, one hundred and seventy-five and sixty-two, respectively, were cured

An imposing array of figures, they prove that

the case against cancer is by no means hopeless, indicating at the same time that as progress in early diagnosis and effective treatment is made, still greater improvement will result

AN INTERESTING SITUATION IN MICHIGAN

At a meeting of the House of Delegates of the Michigan State Medical Society, April 12, 1934, approval of the principles of Health Insurance was voted and the Committee on Medical Economics of this body was instructed to proceed in developing a practical plan relating thereto

In the history of this movement certain facts and details of procedure are of interest

In July, 1933, the Committee on Medical Economics of the Michigan Society was directed "to continue its study, and prepare and present plans for Health Insurance." At this time the House of Delegates adopted the following designated policies for the guidance of the Committee

- 1 Free choice of physician by the insured
- 2 Limitation of benefits to those of medical service
- 3 The control of medical service benefits by the profession
- 4 The exclusion of individuals or organizations that might engage in health insurance for profit

After a meeting in September, 1933, the Committee undertook as its first task this matter of health insurance, and since conflicting reports concerning the validity of the principles of health insurance gave the Committee concern, it was felt that a field study of health insurance in Europe should be conducted. In anticipation of this study the chairman of the Executive Committee of the Michigan Society House of Delegates felt that there should be a meeting in Chicago with representatives of the American Medical Association. This conference was held and is described by Dr Henry A. Luce, speaker of the Michigan House of Delegates in the following words

"The Chairman of the Executive Committee concluded that the subject was one that concerned not only Michigan but all the other states as well. He, therefore, concluded that the best results would be obtained if the Executive Committee met in Chicago with our employees in the national organization. The purpose of such a meeting was obvious. Michigan sought advice and guidance in the solution of its problems

"To me the results of this meeting with our employees were both unsatisfactory and disturbing. Those present, in addition to the Executive Committee and Dr Bruce, were Dr

West, Dr Leland, Dr Woodward and Dr Carey, Ex-President of the A M A

"The Michigan delegation placed its problem before these men and asked for specific information

"The information requested was not forthcoming and the general attitude seemed antagonistic. While Dr West kindly explained the workings of the A M A, the discourse was not on the subject and failed to answer our questions. Dr Leland appeared to be guarding 107 pages of manuscript on the subject of health insurance, but stated he was not in a position to report. Dr Carey magnanimously offered advice that seemed to be a bit gratuitous. He said that we should thoroughly thrash out the whole subject, that we should not involve ourselves, and that Michigan should delay lest it get into trouble. In short, the advice was 'Do nothing'. All this, of course, gave little information and less comfort to the Michigan Executive Committee. During the discussion, Dr Bruce asked Dr West certain questions concerning the publications of the A M A, and the answers were anything but satisfactory. The representative of the A M A assured the Executive Committee of the Michigan State Medical Society that they had no objection to Michigan making an independent study of European plans."

Six days later Dr Henry A Luce and Dr Nathan Sinai went abroad for a study of Health Insurance, and on their return submitted a report to the Economics Committee of the House of Delegates of the Michigan Society, February 23, 1934, and a copy was forwarded to the Executive Committee of the Board of Trustees of the A M A.

A copy of this report appears in the supplement of the *Journal of the Michigan State Medical Society* for May, 1934. This report should be carefully read by all interested in health insurance, because it sets forth the evolution of the present plan in operation in England.

On receipt of this Luce Sinai report the Economics Committee prepared a plan with recommendations under the title of "A Plan for Mutual Health Service" which was submitted to the House of Delegates of the State Society, at a special session, April 12, 1934, and signed by the several members of the Committee with Dr Warnshuis as secretary.

This report, a copy of which appears on page 1185 of this issue, of the *New England Journal of Medicine*, after due consideration and prolonged debate was adopted by the House of Delegates by a vote of sixty-two to nine. We hope that it will be studied by doctors and dentists. An interesting feature of this movement is the cooperation of the dentists with the physicians as shown by the financing of the Luce Sinai Commission by a joint grant from the

Michigan State Medical Society and the American College of Dentists. This is evidence of the growing appreciation of the important part which dentists play in health problems.

After the acceptance of the report of the Economics Committee, the House of Delegates adopted a resolution directing this committee to prepare and present a budget for completing the study of the program outlined in the report and make plans for carrying the recommendations into operation.

Thus far the Michigan movement is apparently waiting to learn of any reaction of the House of Delegates of the American Medical Association to the report which was forwarded to the officers of that body, and the creating of a budget for trials of the suggested plans in some of the counties of Michigan.

Here is evidence of concentration of constructive medical interest in some phases of so called health insurance under the direction of a state medical society.

It seems strange that organized medicine in this country has been loath to take the initiative in adopting some plan which, under medical guidance, might serve the interests of certain groups in their health problems. A definite obstructive attitude has been evident on many occasions with bitter and uncompromising criticism. The history of health insurance in other countries has placed the medical profession in an unfortunate position from which it has been only partly extricated.

Michigan has made an effort to build a constructive program based on the recognition of her responsibility to meet local conditions.

The reaction of the House of Delegates of the American Medical Association to this movement of one of its constituent societies will be watched with interest. Since the Michigan Society has taken steps to have this plan considered by the legislative and executive body of the A M A, the delegates of other state societies ought to be familiar with the plan presented by the Michigan Society when it comes up for discussion in the meeting of the House of Delegates of the A M A.

ANNUAL MEETING OF THE COUNCIL

The annual meeting of the Council will be held in the Ballroom of the Hotel Bancroft, Worcester, on Tuesday, June 5, 1934, at 12 o'clock, noon

Business

1. Reading record of last meeting in abstract
2. Nominating Committee retire to deliberate

3. Report of Committee on Membership and Finance
4. Reports of committees to consider petitions for restoration to the privileges of fellowship and new committees to be appointed
5. Report of the Treasurer
6. Action on draft of revised By-Laws, submitted to each Councilor with the official program, May 6. A second revision by the committee appointed by the Council
7. Reports of Standing Committees and Special Committees
8. Election of Officers and Orator by ballot
9. Appointment of committees for ensuing year, both Standing and Special
10. Incidental business

WALTER L. BURRAGE, *Secretary*
Brookline, May 29, 1934

Councilors are asked to sign one of the two attendance books before the meeting

MISCELLANY

REPORT OF THE COMMITTEE ON MEDICAL ECONOMICS TO THE HOUSE OF DELEGATES OF THE MICHIGAN STATE MEDICAL SOCIETY†

MUTUAL HEALTH SERVICE

1. The purpose of Mutual Health Service is to provide, through the agency of a non profit organization health services at agreed costs to employed persons and the families of employed persons whose annual income does not exceed \$_____*

For the purposes of this plan the word "family" is defined as including in addition to the employee, any or all of the following *unemployed and dependent members living in the home of the employee* wife (husband), sons daughters

With the exception of such limitations as are hereinafter provided the term "health services" shall include the services of Doctors of Medicine, Doctors of Dentistry Registered Nurses, Pharmacists, laboratories and hospitals as well as drugs and medical surgical and optical appliances

2. In accordance with the spirit of mutual responsibility between those who provide and those who benefit by the provision of health services the general direction of Mutual Health Service shall be as follows

A Board of Governors

The Board of Governors, the members of which shall serve without pay, shall be constituted as follows

Three (3) Doctors of Medicine elected by the House of Delegates of the Michigan State Medical

†Supplement to Journal Michigan State Medical Society May 1934 Vol. XXVIII No. 5

The upper income limit was placed at \$1500

Society to serve for a period of three years, except that of the first three elected one shall serve for one year, one for two years and one for three years. Thereafter one Doctor of Medicine shall be elected annually for a period of three years.

One (1) Doctor of Dental Surgery elected by the House of Delegates of the Michigan State Dental Society to serve for a period of three years.

One (1) Pharmacist elected by the State Pharmacy Association to serve for a period of three years.

One (1) Registered Nurse elected by the State Nurses Association to serve for a period of three years.

One (1) Hospital Superintendent elected by the State Hospital Association to serve for a period of three years.

The above members of the Board of Governors shall elect for a period of three years two (2) additional members to represent the industries cooperating in Mutual Health Service and two (2) additional members to represent the recipients of health services.

3 Within such limitations as may hereinafter be provided, the general powers and duties of the Board of Governors shall be as follows:

- a The supervision of the administration of Mutual Health Service
- b The appointment of administrative personnel.
- c The preparation of such rules and regulations as may from time to time become necessary to maintain or clarify the purposes of Mutual Health Service
- d The preparation of fee schedules for the particular health services hereinafter described
- e The administration and control of financial matters including the collection, expenditure and investment of funds
- f The appointment of such committees as may be necessary to the proper functioning of Mutual Health Service

4 Local direction in each county or district where Mutual Health Service is maintained shall be by the following committees and a District Mutual Health Committee:

- a Local Medical Committee
- b Local Dental Committee
- c Local Nursing Committee
- d Local Hospital Committee
- e Local Pharmacy Committee

5 Each Local Committee shall be composed of five members elected or appointed for a period of three years by the body represented. In addition to such powers and duties as may hereinafter be provided the general functions of each Local Committee shall be as follows:

- a Local Medical Committee

1 The preparation of lists of general practitioners and of specialists for the provision of medical services

2 The control of the quality of medical service

3 The hearing of and action upon complaints involving physicians or physicians and patients

4 The reference, with recommendations, of those complaints involving a physician and a member of any other professional group to the District Mutual Health Committee

5 The transmission of recommendations dealing with financial matters to the District Mutual Health Committee

(The powers and duties of other Local Committees representing professional groups would be comparable to the above.)

6 The District Mutual Health Committee shall be composed of the chairmen of the Local Committees, who shall elect one (1) additional member to represent the local industries cooperating in Mutual Health Service and one (1) member to represent the local recipients of health services.

The general powers and duties of the District Mutual Health Committee shall be as follows:

- a The hearing of and action upon complaints transmitted by Local Committees
- b The transmission, with recommendations, of matters involving finances to the Board of Governors

7 Any party involved in an action taken by a Local Committee shall have the right to appeal to the District Mutual Health Committee.

Any party involved in an action taken by the District Mutual Health Committee shall have the right to appeal to the Board of Governors.

8 The Board of Governors shall maintain a Local Executive Secretary and such other personnel as may be necessary in each District where Mutual Health Service is established. The Local Executive Secretary shall serve as executive secretary for each Local Committee and the District Mutual Health Committee.

9 The employee shall have the right to choose a general practitioner of medicine and a general practitioner of dentistry. There shall be no restrictions to such freedom of choice except as follows:

- a The general practitioner shall reside in the employee's city or within a reasonable distance from the employee's residence. "Reasonable distance" shall be determined by the Local Committee.
- b The general practitioner shall hold a license to practice his profession in Michigan.
- c The general practitioner shall have signified in writing his intention to provide service in accordance with the plan of Mutual Health Service.

10 The employee shall have the right to change his selection of a general practitioner of medicine or of dentistry in accordance with either of the following procedures:

a. By filing with the Local Executive Secretary a written notice of the intended change 14 days before any of the following dates January 1, April 1, July 1, October 1, requesting a change on any of the above dates and naming the successor to his general practitioner

b. By filing with the Local Executive Secretary a written request for an immediate change, stating the reason or reasons for the request and naming the successor to his general practitioner

11 The general practitioner of medicine or of dentistry chosen by the employee shall have the right to accept or reject the application for his services. If he accepts he shall have the right to subsequently withdraw his acceptance in accordance with the following procedures

a. By filing with the Local Executive Secretary a written notice of his withdrawal 14 days before any of the following dates January 1, April 1, July 1, October 1

b. By filing with the Local Executive Secretary a written request for immediate withdrawal stating his reason or reasons for such withdrawal

12 The names of persons accepted for services by the general practitioners shall be known as the general practitioner's "Family List." The total number of persons on the Family List shall not exceed one thousand (1,000) for any one general practitioner, provided, however, that in those cases where a general practitioner has one or more salaried assistants licensed to practice in Michigan the number of persons on the Family List shall not exceed sixteen hundred (1,600). The District Mutual Medical Committee shall be empowered to increase the limit from 1,600 to 2,000 when, in its judgment, such extension or increase is necessary

13 The general practitioner of medicine shall provide for the persons on his Family List such services as may be reasonably expected according to the standard of the community in which he practices his profession. These services shall include physical examinations, immunity tests, immunizations, prenatal and postnatal care and such services other than those designated as specialists' services provided however that the general practitioner may include specialists' services in accordance with the regulations adopted by the Local Medical or the Local Dental Committees and approved by the Board of Governors

14 Each person on the Family Lists shall be entitled to the following health service

a. Home office and hospital services of a general practitioner of medicine and such services of medical specialists, nurses, pharmacists, laboratories and hospitals as may in the opinion of the general practitioner be necessary provided, however, that certain services shall be limited as follows

1 Hospital services shall not be provided for mental diseases and tuberculosis

2 Hospital services shall include a semi-private or ward bed, operating rooms, medicines, dressings, laboratory and other services that may be provided in the hospital for a period of 21 days during any one year. For any illness requiring hospitalization for more than 21 but less than 90 days, the Mutual Health Service shall pay 75 per cent of the per diem hospital charges

3 The services of a special nurse shall be limited to a period of 30 days during any one year. The services of a visiting nurse shall be limited to 60 days during any one year

4 Drugs shall be prescribed by a Doctor of Medicine to any member of the Family List at a cost of 25 cents for each prescription. The difference, if any, between this cost and the total cost of the prescription shall be paid by Mutual Health Service. Drugs shall be prescribed in accordance with such regulations as may be approved by the Local Medical and the Local Pharmacy Committees

5 The care of any illness or accident provided for under the Workmen's Compensation Act shall be excluded from Mutual Health Service

15 The costs of services shall be borne by the employee or jointly by the employee and his employer. Payments shall be made in advance either weekly, monthly, semi-annually or annually at a rate or rates established by Mutual Health Service

16 For the period of the experiment the annual costs of services per person on the Family Lists shall be \$27.88

17 The annual sum of \$27.88 per person on the Family List shall be expended as follows

Grand Total.....	\$27 88	100	%

18 For each community or area in which Mutual Health Service operates, fee schedules shall be prepared for the following services shown in Paragraph 17

- 1 Specialists' services in Medicine and Dentistry
- 2 Nursing services
- 3 Hospital services
- 4 Drugs, Medical and Surgical Appliances
- 5 Optical services
- 6 Laboratory services

The fee schedules shall be prepared by the Local Committees and transmitted through the District Committee to the Board of Governors for final action

19 Any general practitioner of medicine or of dentistry whose qualification for the provision of any specialist service is approved by the Local Medical or the Local Dental Committee shall be entitled in addition to the capitation fee to 75 per cent of the specialist's fee as shown on the fee schedule

The Local Committee shall have power to grant, reject or withdraw approval for specialist service or services by the general practitioner

20 In the event that the cost for any service is proportionately higher than anticipated the total sum collected for that service shall be pro-rated among the individuals or institutions providing that service. In the event that the cost for any service is lower than anticipated the excess shall be added to the Surplus or expended according to the judgment of the Board of Governors

21 Surplus funds shall be maintained in separate accounts for each area or community and shall be expended or invested by the Board of Governors

22 Two per cent (2%) of the sum allotted to the general practitioners of medicine and dentistry shall be deducted and placed in a "Postgraduate Training Fund". Expenditures from this fund shall be made by the Board of Governors with the advice of the State Medical and State Dental Societies

The Committee feels that in the foregoing program there is presented a temperate policy for the guidance of the medical professions in the United States. It is a policy that preserves the essence of American practice in giving primary consideration to the potential consumers of health services. In this consideration those things that the profession has long cherished because they have been subjected to the retort of experience and have been found satisfactory are not only retained but strengthened. It is the Committee's opinion that the program presented is the studied and constructive answer of the profession to those encroachments upon private practice that have their origin in the unequal distribution of the services the profession commands

If the House of Delegates approves the program, the Committee recommends that the action be given full publicity. Michigan is practically the only industrial state that remains comparatively free of numerous plans and projects for the provision of health services. This freedom can be attributed to no other factor than the action of the Michigan State Medical Society in undertaking constructive studies. It must remain free until the profession

has had the opportunity to experiment. Nothing will insure this freedom as completely as publicity.

At the same time in many other states the profession finds itself in a difficult position. Lacking a constructive program it is easy prey for commercial or political influences. Publicity given to the Michigan program may, therefore, exert a far reaching effect in providing the profession in other states with the methods and materials for combating destructive influences. Against these influences nothing is more effective than the sure weapon of constructive action.

If the program presented is acceptable to the House of Delegates the Committee proposes the following steps in order to begin the experiment as early as possible:

- 1 The discussion of the proposals with employers and employees. Naturally the communities or areas selected for the experiment will depend upon the reception given to the plan by these groups.
- 2 The presentation of the final detailed plan to the House of Delegates.
- 3 The presentation of the plan to the professional groups in the area or areas selected for the experiment.
- 4 The formation of the local and state committees already mentioned.
- 5 The preparation of reports of the House of Delegates during the progress of the plan.
- 6 The preparation of a final report, with recommendations, at the completion of the experiment.

There are certain implications in the plan for Mutual Health Service that merit the attention of the House of Delegates. These deal with the relation of the plan to the care of indigents and to public health activities.

The Committee sees no reason why the plan should not be extended to include the care of indigents. It feels that with few exceptions the profession's method of handling this problem has been hesitant and generally ineffective as a result of the lack of a definite program. It is not necessary to defend the assumption that while a person may be designated as "unemployed and indigent" his health needs differ little from those of his more fortunate neighbor.

It is generally accepted that the responsibility for the health needs of indigent persons rests upon the community. Nor is the responsibility lessened because it has been shifted to the profession in certain communities. Therefore, the Committee recommends that the Local Committees engage in a joint effort to extend Mutual Health Service to indigents. The method of extension is for the community to enter into a contractual arrangement with Mutual Health Service. Such an arrangement will permit the unemployed and indigent person the same relationship to his general practitioner as he enjoys while employed.

The effect of Mutual Health Service upon public health activities is fairly obvious. In brief, it means an expansion of the services of preventive medicine and dentistry by private practitioners and a concentration of public health work upon educational activities. The Committee feels that such concentration will be heartily approved by the public health agencies concerned.

Thought should also be given by the Delegates to the probable development of a movement in the United States toward some form of compulsion with respect to the purchase or distribution of health services. There is little doubt that the movement has gained momentum and that the coming legislative sessions in many states will see bills presented for compulsory health insurance.

If the experiment with Mutual Health Service is successful the profession will be in an exceedingly strong position to direct public opinion and thereby control legislative action in the interests of public welfare. It is obvious that the advantage of controlling medical legislation will lie with the first constructive program presented. If, in addition to being first the program has a record of successful demonstration, the advantage will become great enough to direct legislative action. Only in this manner may the profession hope to successfully combat commercialism and the profit motive in the distribution of health services.

SUPPLEMENTAL REPORT OF THE COMMITTEE

As a supplement to its formal report your Committee presents certain additional items for consideration and action by the House of Delegates.

The first item deals with the matter of the upper limit of income and upon this question Dr. Sinai will present some data for the information of the delegates.

The second question deals with the association of official public health work with Mutual Health Service. It will be noted that public health is not represented on any of the Committees controlling Mutual Health Service. After some discussion of this aspect of Medical Care your Committee concluded that, if the general plan is approved the House of Delegates should decide the following proposal:

That in order to complete and unify all the health services in Michigan the State Health Commissioner should be made a member of the Board of Governors and either the local or county health officer a member of the District Mutual Health Committee.

The third item deals with your Committee's suggestion for publicizing the program for Mutual Health Service.

In addition to its specific studies in Michigan your Committee has collected information on recent developments in medical care in other parts of the United States. Because of its knowledge of these developments your Committee has suggested that if Mutual Health Service is approved by the House

of Delegates, the plan be given as wide publicity as possible.

The purpose of this publicity is twofold: first, to refute the widespread charge that the profession is unwilling to apply the experimental method to any solution of its economic problems, and, second, to offer to the profession and the public a constructive program as a weapon against such harmful trends as are already developed or are in the process of development. Your Committee feels that Mutual Health Service, if adopted by the House of Delegates, is the unanswerable reply to the profession to the charge that it has failed to give studied consideration to the economic problems of medical care. It also feels that this "declaration of principles" is a standard around which both the public and the professions may rally in mutual protection and with mutual confidence.

A brief description of certain of the developments in the country will serve to substantiate the Committee's opinion that a constructive program is at this time a pressing need.

Many county societies have undertaken projects in health insurance with little study and with almost no central or state authority. The county societies cannot be criticized too greatly for this action. It has come in response to the professions and the public's demand "to do something," and in most cases the state societies, being without any program, have been willing to permit the county societies to bear the brunt of any ill-advised action. This situation is particularly acute in the western states.

Your Committee feels that the major danger of this lack of state society direction lies in its tendency to develop commercial competition between groups of physicians and between other professional groups, as well. The results of such commercial competition have been evident for many years in the application of Workmen's Compensation in certain states. It was for this reason that your Committee stressed the comprehensive program with a centralized and professional financial control.

In this same connection, your Committee has noted the development of hospital insurance in over twenty states. There is nothing particularly wrong in the principle of hospital insurance. However, in the absence of a more comprehensive program your Committee feels that hospital insurance can expand in only one direction and that is to include other services. The demand for expansion has already arisen from the insured public. This means that, as additions to services occur, such additions become not a part of a generalized system but a part of hospital insurance and controlled by the agencies of hospital insurance.

Another significant development in this country is reported in the *New York Times* of March 16. The story dealt with the annual meeting of the advisory council of the Milbank Memorial Fund. At this meeting a plan for state controlled compulsory health insurance was presented and discussed. Those

present included Mayor LaGuardia and Harry L. Hopkins, Federal Relief Administrator. To quote from the *Times*

"The plan," Dr. Miller said, "provides for local differences of ability to pay and for the availability of medical facilities by dividing the services into two classes. The first includes those which should be mandatory for the entire state. It would include home and office care by physicians, prescribed drugs and medicines, hospital care where the institutions are available, and maternity benefits for women who remain under continuous prenatal supervision.

"The second class includes those which are permissive and which may be established in local areas, with the approval of the proper authority, when the extension is desired by the local area, when the costs can be financed, and when the competent personnel and facilities are available. This would include specialist services, dentistry, the clinic and the laboratory, home nursing, etc."

* * *

"You aren't going to get health insurance," Mr. Hopkins said, "if you expect people to do it voluntarily. I am convinced that by one bold stroke we could carry the American people along not only for health insurance but also for unemployment insurance. I think it could be done in the next eighteen months."

Whatever may come as a result of the above advocacy, your Committee views Mutual Health Service as the organization with which state or other authorities must deal. The history of compulsory health insurance is a history of disastrous results to the professions because of a lack of unity. It is a history of an organized group dealing with disorganized professional units or with individuals.

A third development in the United States is the drive toward unemployment insurance. Among medical leaders there is a too general apathy toward this movement. If unemployment insurance becomes both widespread and inclusive, your Committee feels that thought must be given by the professions to two items: first, the setting aside of a percentage of unemployment insurance funds to provide medical care for the unemployed, and, second, the question of unemployment by reason of physical disability.

Out of the second item it is not improbable that methods may be developed for the care of physically unemployable people so that they may again become employable. The history of Workmen's Compensation shows that the profession gave little or no thought to its medical aspects. In this connection the following quotation from the report of the Committee on Legislation and Public Policies in *The Journal of the Michigan State Medical Society* for March, 1912, will be of interest:

'True we have had two sessions called by the Governor to consider special and specific subjects yet at these sessions nothing of a medical or public health nature was considered. Nothing at these

sessions could be legally or constitutionally considered other than those recommended from time to time by special message from the Governor to the Legislature. Therefore, if any amendments to our medical laws are to be made they must be made during the next regular session of the Legislature which will convene January, 1913."

It was at one of the special sessions where "nothing of a medical or public health nature was considered" that Michigan adopted the law for Workmen's Compensation. Your Committee presents this item for whatever may be its value in focusing attention upon unemployment insurance.

As reported to the House of Delegates at its last meeting, the California legislature has appointed a commission to study health insurance and report in January, 1935. No further information concerning the activities of the commission is available. The whole subject, however, is on the program of the Western Hospital Association meeting in Sacramento, California, this week, and also at a meeting to be held before the Commonwealth Club in San Francisco on Friday.

Recently the Committee on Medical Economics of the Colorado State Medical Society published a report advocating the application of the principle of health insurance. To quote from this report:

"The point at issue is not the insurance principle but how to use it.

"We are not unmindful of the opposition of the A. M. A. to the general plan of insurance medicine, especially as operated by European governments or by corporations for profit, nor unmindful of the deteriorations accompanying contract practice regardless of how disguised. The plan referred to is not in the opposed classes because it does not restrict opportunity to practice, nor free choice of physician, is on a non profit basis and under the control and management of the profession. This places the responsibility where it belongs. All of us have looked to the A. M. A. for help. Thus far we have been disappointed."

An interesting booklet has been received recently by your Committee. It contains the platform and principles of the Medical League for Socialized Medicine, an organization with headquarters in Brooklyn and with a membership of over 500 physicians. This organization is unequivocally committed to the principle of salaried physicians providing service under the state.

These are a few of the evidences of the turmoil in medical economics. It is for its quieting and beneficial influence that your Committee has recommended that the plan of Mutual Health Service be widely publicized.

RESOLUTION OF APPROVAL

Whereas, the House of Delegates of the Michigan State Medical Society, at its meeting on July 12 1933, directed the Committee on Medical Economics to prepare and present for consideration of

the House a plan or plans for health insurance, and
Whereas, the House of Delegates adopted the policies for the guidance of its Committee on Medical Economics
and

Whereas, the plan for Mutual Health Service presented by the Committee on Medical Economics is in accord with the above policies therefore, be it

Resolved that the House of Delegates of the Michigan State Medical Society approves the general principles of the plan for Mutual Health Service, and directs the Committee on Medical Economics to undertake the following efforts

- a The discussion of the plan with employers and employees
- b The determination of the legal status of the Mutual Health Service, and the necessary legal action for the organization of Mutual Health Service
- c Preparation of the final detail plan of the Mutual Health Service and its presentation to the House of Delegates for final action,

and be it further

Resolved, that the plan for Mutual Health Service shall not be inaugurated in any county without the approval of the county and state medical society

AN HONOR TO DR GEORGE GILBERT SMITH

At the meeting of the American Urological Association, held at Atlantic City, May 25, Dr George Gilbert Smith of Boston was elected president. Dr Smith is a member of the staff of the Massachusetts General Hospital, Department of Urology

CORRESPONDENCE

The Massachusetts Medical Society

POSTGRADUATE INSTRUCTION

May 26, 1934

Editor, *New England Journal of Medicine*,

On May 15, 1934 the Massachusetts Medical Society's first year of organized postgraduate extension courses came to a close. One thousand and two Fellows were enrolled which may be considered a successful beginning. The Executive Committee has prepared a report of the year's work which will be submitted to the Council on June 5.

Some comments by those who took the course may be of interest

- 1) "Looking forward to next year's lectures"
- 2) "I want practical everyday talk, not too many statistics"
- 3) Course worth while. All members of Massachusetts Medical Society should be compelled to take this course"
- 4) Suggest an outline of year's lectures be mailed each doctor in advance"

- 5) "I believe the course was too elementary"
- 6) "Most excellent undertaking and would greatly appreciate more"
- 7) "Well worth while. Valuable and stimulating as such things always are when given by good men."
- 8) "The choice of speakers was happy—men who were practical rather than didactic"
- 9) "Make them more useful and practical for the family physician"
- 10) "I favor more questions, some of the points that helped me most were unearthed by questions"
- 11) "In my opinion postgraduate teaching does not mean reading papers. Each instructor should come with his subject prepared so that he can stand up and give it without notes or with notes. I feel that the instructor should not attempt to cover too much ground"
- 12) "I think the courses were too general, would prefer more details of diagnosis and treatment"
- 13) From a district chairman "First, in my opinion this was one of the finest courses ever afforded to the physicians in our County, and I am convinced from many remarks made to me from the majority of the men, and from men whose opinions I value most, that the course was appreciated and will be looked forward to in the years to come. I am sure next year we will have a much larger turnout."
- 14) From another district chairman "The talks have been very excellent in every way and have been much enjoyed by all of the men and they feel that it is one of the best things that the Massachusetts Medical Society in association with the District Societies has ever put over. It has done much to bring the men together, and to promote harmony and good fellowship, and this is a very important thing in any community undertaking. The local men have tried to express their appreciation in various ways for the efforts that have been made by the different speakers in making such long trips to carry out this program"

The following letter from a Rhode Island doctor who took the course at Fall River is of interest

"I had the opportunity to attend the lectures sponsored by the Massachusetts Medical Society on specialized medical subjects, given at Fall River. I take this occasion for congratulating the Society for such a step forward

"All the lecturers were very interesting and they all presented their respective subjects in such a way that the important facts were emphasized. I need not say any more because these physicians are already known.

"I sincerely hope that this will become a tradition, and that next year we shall again enjoy the same privilege of being taught the best things by the best men."

The program for next year will be published before the autumn. Anyone interested in special subjects should consult his district chairman on postgraduate instruction. The final report will be posted in the exhibit space at the Worcester Convention.

Sincerely yours,

LEROY E PARKINS, M.D., *Secretary*,
Executive Committee
on Postgraduate Instruction

THE NECESSITY FOR THE JUDICIOUS USE OF ARTIFICIAL PNEUMOTHORAX

May 24, 1934

Editor, *New England Journal of Medicine*

In the *Journal* of May 17, 1934 Drs Walter C Bailey and Bayard T Crane of the Central New England Sanatorium called attention to the physicians of New England that they will accept cases of early tuberculosis for deflation treatment without cost of any kind to the patient. They propose to keep these patients at the sanatorium for ten days or two weeks and then return them to the family physician for refills and further care. By deflation I suppose they mean artificial pneumothorax treatment and in this way suggest that pneumothorax treatment should become the universal practice of every family physician. They do not mention any period of observation prior to instituting pneumothorax and infer that every patient should be ready to go back to his or her home after a brief stay of ten days or two weeks.

Those of us who have had some experience in the treatment of pulmonary tuberculosis do not as yet feel that collapse therapy should be used in every instance. Artificial pneumothorax is only one form of collapse therapy. A goodly number of patients if found in the early stages will do well on sanatorium régime alone. They make no mention of selecting patients, but will abide by the family physician's order for pneumothorax treatment. As yet I feel that collapse treatment is only an adjunct, to be sure a very important one, to the general treatment, and should be distinctly in the hands of those who are experienced in the general treatment of tuberculosis.

While the technical part of this treatment is a simple one, untold damage may be done by its in judicious use. The problem of the effectiveness of this treatment is a very serious one. The question of dosage is of extreme importance, and the

question also of intervals is a very serious one to decide. Then there are always complications to treat, such as effusions.

The mere compression of the lung does not necessarily mean that the affected lesion has been well taken care of, adhesions frequently preventing a good collapse. Other forms of collapse therapy, if pneumothorax treatment fails, must be considered. A shifting mediastinum may also become a very irksome problem, the whole lung may simply be pushed over rather than compressed. Frequent fluoroscopic examinations before and after refills are of the greatest importance. The technical procedure itself is not without its real dangers. Lungs have been punctured and air emboli may occur. The length of treatment is a very delicate and a very important problem. Space will not allow enumeration of the many factors that will make for the success or failure in the treatment of pulmonary tuberculosis.

It has been a hard battle to bring the profession to the realization of the importance of collapse therapy in pulmonary tuberculosis. Let us not go too far now and destroy a method of treatment which has been a real blessing to the tuberculous patient by its injudicious, untrained and inexperienced use.

Sincerely yours

MOSES J STONE, M.D.

FELLOWSHIPS AT THE HARVARD MEDICAL SCHOOL

To the Editor

The Commonwealth Fund of New York has added a course in office surgery to the list of subjects which are available for fellowships at the Harvard Medical School, Courses for Graduates. This course is designed for physicians who are engaged in general practice. The subjects studied will be surgical problems met in office practice. The course is for one month.

The other courses for which fellowships are available are medicine, obstetrics and pediatrics. Fellowships are for one to four months. The stipend is two hundred and fifty dollars per month plus tuition and traveling expenses from place of residence to Boston and return.

An applicant for a fellowship must be a graduate of a grade A medical school, a member of the Massachusetts Medical Society, in good standing, must have been in practice at least five years, should be between thirty and fifty years of age, and resident of a town of under ten thousand population.

Application blanks may be obtained from the Commonwealth Fund, 41 East 57th Street, New York City or from the Courses for Graduates, Harvard Medical School, 25 Shattuck Street, Boston.

Sincerely yours

LEROY E PARKINS, M.D.,
*Secretary to Courses for Graduates
under the Commonwealth Fund.*

RECENT DEATHS

SMITH—JOSEPH ANDREW SMITH, M D of 584 Cambridge Street, Worcester, Massachusetts, with an office at 476 Main Street, died in that city, April 16 1934. He was born in Worcester in 1875 and was educated at the Worcester public schools, Holy Cross College and the Philadelphia College of Dental Surgery. His M D degree was conferred by the College of Physicians and Surgeons of Boston in 1914. His hospital training included two and a half years in the outpatient department of the Boston City Hospital. He joined the Massachusetts Medical Society in 1920, and specialized in oral surgery.

He served as police surgeon for several years and had an extended military service, first as an enlisted private in the Spanish American War, and was assigned to Fort McPherson Georgia. Camp Hobson Georgia and Plattsburg New York. On returning to Worcester he was appointed as paymaster of the First Battalion M V N, with the rank of lieutenant and later promoted to that of captain and retired from service with the rank of major. He was very much interested in the Boy Scouts and Red Cross activities, and was prominent in politics. He served on the Worcester school board. He was a member of Alhambra Council K. of C., the Eagles Division 25 A O H E R Shumway Camp United States War Veterans the Economic Club, McCafferty Court M C O F the Electric Medical Society the Worcester District Dental Society and was a founder of the St. Vincent de Paul Society of Sacred Heart Church.

He is survived by his widow Mrs Mary J (Dunn) Smith and three children Mary Joseph and Lewis A. two brothers, Rev Thomas P Smith of Blackstone and Rev William F Smith of Oakdale and a sister, Miss Julia Smith of Worcester.

HILL—GEORGE HILLARD HILL, M.D., of 15 High Street Worcester, Massachusetts died in that city May 18 1934 after an illness of several months terminating in pneumonia. He was born in Worcester in 1868 the son of J Henry Hill and Sarah Bruce (Jenkins) Hill. He was educated in Kings private school Leicester Academy and graduated from the Harvard Medical School in 1894. He first practiced in Millis and moved to Worcester in 1897. He served on the staffs of the Memorial and the Worcester City Hospitals but resigned from hospital service several years ago devoting much of his time to the duties of surgeon to the Worcester Fire Department reporting at all fires even at times when his health had become seriously impaired.

He joined the Massachusetts Medical Society in 1896 and the American Medical Association the same year. He was a Fellow of the American College of Surgeons, and a member of the Harvard Club of Worcester Devens Post A. L. the Leicester Golf Club, and Cohasset Golf Club of Southbridge.

He is survived by his widow Grace R E (El

Hott) Hill, and three nephews, Southworth Lancaster Bruce Lancaster, and Eveleth D Hill all of Worcester.

NEWTON—EDWARD ROSWELL NEWTON, M D of Brookline, Massachusetts, with an office at 419 Boylston Street, Boston, died at his home, May 19, 1934 after a long illness. He was born in Hartford, Connecticut, in 1874 and graduated in medicine from the Harvard Medical School in 1898. After post-graduate studies in Berlin, Vienna and Paris in diseases of the nose, throat, and ear, he practiced in Boston.

During the World War he served in the United States Navy and practiced his specialty.

He joined the Massachusetts Medical Society in 1914. He was a Fellow of the American Medical Association and a member of the American Otological Society. He is survived by his widow, Mrs Mabelle M (Field) Newton, three brothers and two sisters.

DENIG—BLANCHE A. DENIG, M.D. formerly of Boston, and lately living at Oakland California died recently.

She was born in Columbus, Ohio. While in Boston she had offices at 541 Boylston Street, and was a member of the staff of the New England Hospital for Women and Children.

OSTROM—HJALMAR OSTROM, M.D. of Quincy Massachusetts, with an office at 419 Boylston Street, Boston died at the New England Baptist Hospital, May 24 1934.

Dr Ostrom was born in Sweden in 1882 and came to the United States when he was seventeen years of age. He studied for three years in the Morgan Park Theological School and graduated in medicine from the Creighton University School of Medicine in 1911. Soon after graduation he served as a missionary to the Belgian Congo for seventeen years representing the American Baptist Foreign Missionary Society. While there he was decorated by the late King Albert for meritorious service both as a missionary and for his medical work in combating disease in that territory. During a leave of absence he studied tropical diseases at Harvard College London and Brussels. He retired from the foreign field and engaged in practice in Quincy in 1929. He joined the Massachusetts Medical Society in 1930.

Dr Ostrom is survived by his widow Mrs Agnes (Brodd) Ostrom and two daughters, Miss Mary Ann and Miss Helen Ostrom.

SIMMONS—FRED ALBERT SIMMONS, M.D. 101 Bay State Road Boston Massachusetts died at his home, May 27 1934 after an illness of two days.

Dr Simmons was born in North Adams in 1877 and was educated in the public schools of Adams, and at Brown University graduating with the de-

"All the lecturers were very interesting and they all presented their respective subjects in such a way that the important facts were emphasized. I need not say any more because these physicians are already known

"I sincerely hope that this will become a tradition, and that next year we shall again enjoy the same privilege of being taught the best things by the best men"

The program for next year will be published before the autumn. Anyone interested in special subjects should consult his district chairman on postgraduate instruction. The final report will be posted in the exhibit space at the Worcester Convention.

Sincerely yours,

LEROY E. PARKINS, M.D., Secretary,
Executive Committee
on Postgraduate Instruction.

THE NECESSITY FOR THE JUDICIOUS USE OF ARTIFICIAL PNEUMOTHORAX

May 24, 1934

Editor, *New England Journal of Medicine*

In the *Journal* of May 17, 1934 Drs. Walter C. Bailey and Bayard T. Crane of the Central New England Sanatorium called attention to the physicians of New England that they will accept cases of early tuberculosis for deflation treatment without cost of any kind to the patient. They propose to keep these patients at the sanatorium for ten days or two weeks and then return them to the family physician for refills and further care. By deflation I suppose they mean artificial pneumothorax treatment and in this way suggest that pneumothorax treatment should become the universal practice of every family physician. They do not mention any period of observation prior to instituting pneumothorax and infer that every patient should be ready to go back to his or her home after a brief stay of ten days or two weeks.

Those of us who have had some experience in the treatment of pulmonary tuberculosis do not as yet feel that collapse therapy should be used in every instance. Artificial pneumothorax is only one form of collapse therapy. A goodly number of patients if found in the early stages will do well on sanatorium régime alone. They make no mention of selecting patients but will abide by the family physician's order for pneumothorax treatment. As yet I feel that collapse treatment is only an adjunct, to be sure a very important one to the general treatment, and should be distinctly in the hands of those who are experienced in the general treatment of tuberculosis.

While the technical part of this treatment is a simple one, untold damage may be done by its injudicious use. The problem of the effectiveness of this treatment is a very serious one. The question of dosage is of extreme importance, and the

question also of intervals is a very serious one to decide. Then there are always complications to treat, such as effusions.

The mere compression of the lung does not necessarily mean that the affected lesion has been well taken care of, adhesions frequently preventing a good collapse. Other forms of collapse therapy, if pneumothorax treatment fails, must be considered. A shifting mediastinum may also become a very irksome problem; the whole lung may simply be pushed over rather than compressed. Frequent fluoroscopic examinations before and after refills are of the greatest importance. The technical procedure itself is not without its real dangers. Lungs have been punctured and air emboli may occur. The length of treatment is a very delicate and a very important problem. He was very much interested in the Boy Scouts and Red Cross activities, and was prominent in politics. He served on the Worcester school board. He was a member of Alhambra Council K. of C., the Eagles Division 25, A. O. H. E. R., Shumway Camp, United States War Veterans, the Economic Club, McCafferty Court, U. C. O. F., the Electric Medical Society, the Worcester District Dental Society and was a founder of the St. Vincent de Paul Society of Sacred Heart Church.

He is survived by his widow Mrs. Mary J. (Dunn) Smith and three children, Mary Joseph and Lewis A., two brothers, Rev. Thomas P. Smith of Blackstone and Rev. William F. Smith of Oakdale, and a sister, Miss Julia Smith of Worcester.

HILL—GEORGE HILLIARD HILL, M.D. of 15 High Street, Worcester, Massachusetts, died in that city, May 18 1934, after an illness of several months terminating in pneumonia. He was born in Worcester in 1868, the son of J. Henry Hill and Sarah Bruce (Jenkins) Hill. He was educated in Kings private school, Leicester Academy and graduated from the Harvard Medical School in 1894. He first practiced in Millis and moved to Worcester in 1897. He served on the staffs of the Memorial and the Worcester City Hospitals but resigned from hospital service several years ago, devoting much of his time to the duties of surgeon to the Worcester Fire Department, reporting at all fires, even at times when his health had become seriously impaired.

He joined the Massachusetts Medical Society in 1896 and the American Medical Association the same year. He was a Fellow of the American College of Surgeons and a member of the Harvard Club of Worcester, Devens Post, A. L., the Leicester Golf Club, and Cohasset Golf Club of Southbridge.

He is survived by his widow, Grace R. E. (El-

liott) Hill, and three nephews, Southworth Lancaster, Bruce Lancaster, and Eveleth D. Hill, all of Worcester.

NEWTON—EDWARD ROSWELL NEWTON, M.D. of Brookline, Massachusetts, with an office at 419 Boylston Street, Boston, died at his home, May 19, 1934, after a long illness. He was born in Hartford, Connecticut, in 1874 and graduated in medicine from the Harvard Medical School in 1898. After post graduate studies in Berlin, Vienna and Paris in diseases of the nose, throat, and ear, he practiced in Boston.

During the World War he served in the United States Navy and practiced his specialty.

He joined the Massachusetts Medical Society in 1914. He was a Fellow of the American Medical Association and a member of the American Otological Society. He is survived by his widow, Mrs. Mabelle M. (Field) Newton, three brothers and two sisters.

DENIG—BLANCHE A. DENIG, M.D., formerly of Boston and lately living at Oakland, California, died recently.

She was born in Columbus, Ohio. While in Boston she had offices at 541 Boylston Street, and was a member of the staff of the New England Hospital for Women and Children.

OSTROM—HJALMAR OSTROM, M.D., of Quincy, Massachusetts, with an office at 419 Boylston Street, Boston, died at the New England Baptist Hospital, May 24 1934.

Dr. Ostrom was born in Sweden in 1882 and came to the United States when he was seventeen years of age. He studied for three years in the Morgan Park Theological School, and graduated in medicine from the Creighton University School of Medicine in 1911. Soon after graduation he served as a missionary to the Belgian Congo for seventeen years, representing the American Baptist Foreign Missionary Society. While there he was decorated by the late King Albert for meritorious service both as a missionary and for his medical work in combating disease in that territory. During a leave of absence he studied tropical diseases at Harvard College, London and Brussels. He retired from the foreign field and engaged in practice in Quincy in 1929. He joined the Massachusetts Medical Society in 1930.

Dr. Ostrom is survived by his widow, Mrs. Agnes (Brodd) Ostrom, and two daughters, Miss Mary Ann and Miss Helen Ostrom.

SIMMONS—FRED ALBERT SIMMONS, M.D., 101 Bay State Road, Boston, Massachusetts, died at his home, May 27 1934, after an illness of two days.

Dr. Simmons was born in North Adams in 1877, and was educated in the public schools of Adams, and at Brown University, graduating with the de-

"All the lecturers were very interesting and they all presented their respective subjects in such a way that the important facts were emphasized. I need not say any more because these physicians are already known

"I sincerely hope that this will become a tradition, and that next year we shall again enjoy the same privilege of being taught the best things by the best men"

The program for next year will be published before the autumn. Anyone interested in special subjects should consult his district chairman on postgraduate instruction. The final report will be posted in the exhibit space at the Worcester Convention.

Sincerely yours,

LEROY E PARKINS, M D, *Secretary,*
Executive Committee
on Postgraduate Instruction

THE NECESSITY FOR THE JUDICIOUS USE OF ARTIFICIAL PNEUMOTHORAX

May 24, 1934

Editor, *New England Journal of Medicine*

In the *Journal* of May 17, 1934 Drs Walter C Bailey and Bayard T Crane of the Central New England Sanatorium called attention to the physicians of New England that they will accept cases of early tuberculosis for *deflation* treatment without cost of any kind to the patient. They propose to keep these patients at the sanatorium for ten days or two weeks and then return them to the family physician for refills and further care. By deflation I suppose they mean artificial pneumothorax treatment and in this way suggest that pneumothorax treatment should become the universal practice of every family physician. They do not mention any period of observation prior to instituting pneumothorax and infer that every patient should be ready to go back to his or her home after a brief stay of ten days or two weeks.

Those of us who have had some experience in the treatment of pulmonary tuberculosis do not as yet feel that collapse therapy should be used in every instance. Artificial pneumothorax is only one form of collapse therapy. A goodly number of patients if found in the early stages will do well on sanatorium régime alone. They make no mention of selecting patients, but will abide by the family physician's order for pneumothorax treatment. As yet I feel that collapse treatment is only an adjunct, to be sure a very important one to the general treatment, and should be distinctly in the hands of those who are experienced in the general treatment of tuberculosis.

While the technical part of this treatment is a simple one, untold damage may be done by its injudicious use. The problem of the effectiveness of this treatment is a very serious one. The question of dosage is of extreme importance, and the

question also of intervals is a very serious one to decide. Then there are always complications to treat, such as effusions.

The mere compression of the lung does not necessarily mean that the affected lesion has been well taken care of, adhesions frequently preventing a good collapse. Other forms of collapse therapy, if pneumothorax treatment fails, must be considered. A shifting mediastinum may also become a very irksome problem, the whole lung may simply be pushed over rather than compressed. Frequent fluoroscopic examinations before and after refills are of the greatest importance. The technical procedure itself is not without its real dangers. Lungs have been punctured and air emboli may occur. The length of treatment is a very delicate and a very important problem. Space will not allow enumeration of the many factors that will make for the success or failure in the treatment of pulmonary tuberculosis.

It has been a hard battle to bring the profession to the realization of the importance of collapse therapy in pulmonary tuberculosis. Let us not go too far now and destroy a method of treatment which has been a real blessing to the tuberculous patient by its injudicious, untrained and inexperienced use.

Sincerely yours,

MOSES J STONE, M D

FELLOWSHIPS AT THE HARVARD MEDICAL SCHOOL

To the Editor

The Commonwealth Fund of New York has added a course in office surgery to the list of subjects which are available for fellowships at the Harvard Medical School Courses for Graduates. This course is designed for physicians who are engaged in general practice. The subjects studied will be surgical problems met in office practice. The course is for one month.

The other courses for which fellowships are available are medicine, obstetrics and pediatrics. Fellowships are for one to four months. The stipend is two hundred and fifty dollars per month plus tuition and traveling expenses from place of residence to Boston and return.

An applicant for a fellowship must be a graduate of a grade A medical school, a member of the Massachusetts Medical Society in good standing, must have been in practice at least five years, should be between thirty and fifty years of age, and resident of a town of under ten thousand population.

Application blanks may be obtained from the Commonwealth Fund, 41 East 57th Street, New York City, or from the Courses for Graduates, Harvard Medical School, 25 Shattuck Street, Boston.

Sincerely yours,

LEROY E PARKINS, M D

*Secretary to Courses for Graduates
under the Commonwealth Fund.*

RECENT DEATHS

SMITH—JOSEPH ANDREW SMITH, M D of 584 Cambridge Street Worcester, Massachusetts, with an office at 476 Main Street, died in that city, April 16 1934 He was born in Worcester in 1875 and was educated at the Worcester public schools, Holy Cross College and the Philadelphia College of Dental Surgery His M.D degree was conferred by the College of Physicians and Surgeons of Boston in 1914 His hospital training included two and a half years in the outpatient department of the Boston City Hospital He joined the Massachusetts Medical Society in 1920 and specialized in oral surgery

He served as police surgeon for several years and had an extended military service, first as an enlisted private in the Spanish American War and was assigned to Fort McPherson Georgia Camp Hobson, Georgia and Plattsburg New York On returning to Worcester he was appointed as pay master of the First Battalion M V M, with the rank of lieutenant and later promoted to that of captain, and retired from service with the rank of major He was very much interested in the Boy Scouts and Red Cross activities and was prominent in politics He served on the Worcester school board He was a member of Alhambra Council K. of C., the Eagles Division 25 A O H E R Shumway Camp, United States War Veterans the Economic Club McCafferty Court M C O F the Electric Medical Society the Worcester District Dental Society and was a founder of the St Vincent de Paul Society of Sacred Heart Church

He is survived by his widow Mrs Mary J (Dunn) Smith and three children Mary, Joseph and Lewis A two brothers Rev Thomas P Smith of Blackstone, and Rev William F Smith of Oakdale, and a sister Miss Julia Smith of Worcester

HILL—GEORGE HILLARD HILL M D of 15 High Street Worcester, Massachusetts died in that city May 18 1934 after an illness of several months terminating in pneumonia He was born in Worcester in 1868 the son of J Henry Hill and Sarah Bruce (Jenkins) Hill He was educated in Kings private school Leicester Academy and graduated from the Harvard Medical School in 1894 He first practiced in Mills and moved to Worcester in 1897 He served on the staffs of the Memorial and the Worcester City Hospitals but resigned from hospital service several years ago devoting much of his time to the duties of surgeon to the Worcester Fire Department reporting at all fires even at times when his health had become seriously impaired

He joined the Massachusetts Medical Society in 1896 and the American Medical Association the same year He was a Fellow of the American College of Surgeons and a member of the Harvard Club of Worcester Devens Post, A. L. the Leicester Golf Club and Cohasset Golf Club of Southbridge

He is survived by his widow Grace R E (El

lott) Hill and three nephews, Southworth Lancaster, Bruce Lancaster, and Eveleth D Hill, all of Worcester

NEWTON—EDWARD ROSWELL NEWTON, M D, of Brookline, Massachusetts, with an office at 419 Boylston Street, Boston, died at his home, May 19, 1934, after a long illness He was born in Hartford, Connecticut, in 1874, and graduated in medicine from the Harvard Medical School in 1898 After post graduate studies in Berlin Vienna and Paris in diseases of the nose throat, and ear, he practiced in Boston

During the World War he served in the United States Navy and practiced his specialty

He joined the Massachusetts Medical Society in 1914 He was a Fellow of the American Medical Association and a member of the American Otological Society He is survived by his widow, Mrs Mabelle M (Field) Newton three brothers and two sisters

DENIG—BLANCHE A. DENIG M D, formerly of Boston and lately living at Oakland, California, died recently

She was born in Columbus, Ohio While in Boston she had offices at 541 Boylston Street, and was a member of the staff of the New England Hospital for Women and Children

OSTROM—HJALMAR OSTROM M D of Quincy, Massachusetts with an office at 419 Boylston Street, Boston died at the New England Baptist Hospital, May 24 1934

Dr Ostrom was born in Sweden in 1882, and came to the United States when he was seventeen years of age He studied for three years in the Morgan Park Theological School, and graduated in medicine from the Creighton University School of Medicine in 1911 Soon after graduation he served as a missionary to the Belgian Congo for seventeen years representing the American Baptist Foreign Missionary Society While there he was decorated by the late King Albert for meritorious service both as a missionary and for his medical work in combating disease in that territory During a leave of absence he studied tropical diseases at Harvard College London and Brussels He retired from the foreign field and engaged in practice in Quincy in 1929 He joined the Massachusetts Medical Society in 1930

Dr Ostrom is survived by his widow Mrs Agnes (Brodd) Ostrom and two daughters, Miss Mary Ann and Miss Helen Ostrom

SIMMONS—FRED ALBERT SIMMONS M D 101 Bay State Road Boston Massachusetts died at his home, May 27 1934 after an illness of two days

Dr Simmons was born in North Adams in 1877, and was educated in the public schools of Adams, and at Brown University, graduating with the de-

gree of Ph.B., and received his M.D. degree from Columbia University College of Physicians and Surgeons in 1903. He practiced in Brockton, Massachusetts, for several years, later settling in Boston where he specialized in otology, laryngology and rhinology, and was formerly an instructor in otology at the Harvard Medical School, and associate surgeon at the Massachusetts Eye and Ear Infirmary, and associate surgeon at the Massachusetts General Hospital. He served as corporal in the Spanish American War, and was a member of the medical advisory board during the World War.

He joined the Massachusetts Medical Society in 1905, and was a Fellow of the American Medical Association, a Fellow of the American Board of Otolaryngology, and a member of the New England Otological, Laryngological and Rhinological Society.

He belonged to the Commercial Club, the University Club, the Thorney Lean Golf Club of Brockton, and the Harvard Club. He was prominent in the Masonic fraternity and the Knights of Pythias.

Dr. Simmons is survived by his widow, Mrs. Geneva (Cobb) Simmons, one son, Dr. Fred A. Simmons, Jr., two brothers, Louis A. Simmons, of North Adams, and Arthur C. Simmons of Adams, and a sister, Miss Edith M. Simmons, of Adams.

ANNUAL MEETING

PROGRAM FOR THE ENTERTAINMENT OF THE VISITING WOMEN

Monday, June 4

9 A.M. to 12 M. The local women's committee will be at the Hotel Bancroft to welcome and assist the visitors.

12 M. A bus will take visitors to the following:
The Library of the American Antiquarian Society

Tatnuck Country Club for luncheon at one o'clock.

The J. W. Higgins Armory Museum
The Worcester Art Museum

The Worcester Club for tea about 4:30

8 P.M. The Shattuck Lecture Hotel Bancroft, Worcester

Tuesday, June 5

9 A.M. to 12 M. The local women's committee will be in the hotel lobby to welcome and assist the visitors.

12 M. A bus will take visitors to the following:
The Worcester Memorial Auditorium
The Worcester Country Club for luncheon at one-thirty o'clock.

The gardens of Mrs. Homer Gage in Shrewsbury at about three o'clock.

7 P.M. The Annual Dinner

The galleries of the ballroom have been reserved for ladies who wish to hear the distinguished after dinner speakers.

REMOVAL

M. A. WEINGER, M.D., announces the removal of his office from 371 Commonwealth Avenue to 395 Commonwealth Avenue, Boston.

REPORTS AND NOTICES OF MEETINGS

OFFICERS OF THE NEW ENGLAND PHYSICAL THERAPY SOCIETY

At the annual meeting of the New England Physical Therapy Society held May 16, 1934, the following officers were elected: Dr. Charles W. McClure of Boston, president, Dr. George B. Carr of Lynn, and Dr. George B. Rice of Boston, vice-presidents, Dr. Arthur H. Ring of Arlington, secretary, Dr. Franklin P. Lowry of Newton, treasurer.

The councillors are, for three years, Dr. William G. Curtis, Wollaston, and Dr. DeWitt G. Wilcox, Newton, for two years, Dr. John L. O'Toole, Haverhill, and Dr. Solon Abbott, Franklin, for one year, Dr. William D. McFee, Boston, and Dr. John F. Valentine, Danvers.

Dr. William L. Clark, Philadelphia, was elected to Honorary Membership in the Society.

MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS

At the meeting of the Massachusetts Society of Examining Physicians, May 23, 1934, Dr. J. E. Goldthwait delivered an address under the title of "Chronic Invalidism Due to Joint Pathology." The discussion was opened by Dr. Howard Thompson who spoke on the medical aspects of the subject. He was followed by Dr. Carl Watson who presented the osteopathic point of view.

The officers elected for the ensuing year are:

Dr. Frederick W. O'Brien of Boston, president, Dr. George H. R. Gosman of Waban, Dr. James R. Knowles, and Dr. Bernard A. Godwin of Boston, vice-presidents, Dr. William Pearce Coues of Brookline, secretary, and Dr. Robert C. Gwin of Brookline, treasurer. The following were elected councillors: Dr. Francis R. Mahony of Lowell, Dr. John W. McNamara of Brockton, and Drs. Arl W. George, William F. Cotting, Samuel Tartakoff, Michael E. McGarty, George W. Morse, all of Boston.

THE ANNUAL MEETING OF THE NATIONAL TUBERCULOSIS ASSOCIATION

Seven hundred and sixty-six persons from all parts of the country registered at the Thirtieth Annual Meeting of the National Tuberculosis Association.

held at Hotel Netherland Plaza in Cincinnati, Ohio, on May 14, 15, 16, and 17

The American Sanatorium Association and the National Conference of Tuberculosis Secretaries also met at the same place on Monday, May 14

Those in attendance from Massachusetts included Dr Henry D Chadwick, State Commissioner of Public Health Dr Sumner H Remick, Superintendent, Middlesex County Sanatorium, Dr Edson W Glidden, Superintendent, Worcester County Sanatorium Dr Olin S Pettingill, Superintendent Essex County Sanatorium, Miss Ida Cannon, Chief Social Service Department, Massachusetts General Hospital, Dr John B Hawes, 2nd, President, Boston Tuberculosis Association, Miss Jean V Latimer, Educational Secretary, and Frank Kiernan, Executive Secretary, Massachusetts Tuberculosis League

Dr John B Hawes, 2nd gave a paper in the Clinical Section on "Dust and Its Relation to Tuberculosis" Dr Henry D Chadwick was called upon to comment on papers in the Clinical, Pathological and Sociological Sections Miss Jean V Latimer spoke at the Health Education Meeting of Tuberculosis Secretaries Mr Frank Kiernan, who was Chairman of the Sociological Section, presided at the sessions on Tuesday and Thursday and also spoke on the program of the National Conference of Tuberculosis Secretaries

Dr H Kennon Dunham of Cincinnati, Ohio, was elected President of the National Tuberculosis Association for 1934-35, Dr Edward S McSweeney of New York was elected President of the American Sanatorium Association, and Mr Ernest D Easton of Newark, New Jersey, was elected President of the National Conference of Tuberculosis Secretaries All three organizations will come together again in June, 1935, for their Annual Meetings at Saranac Lake, New York

NEW ENGLAND PHYSICAL THERAPY SOCIETY

The June meeting of the New England Physical Therapy Society will be held at the Hotel Bancroft Worcester, in conjunction with the program of the Section of Radiology and Physical Therapy of the Massachusetts Medical Society at 2 P M on Monday, June 4

This will be the final gathering of the year All members of our Society should make an effort to be present.

ARTHUR H. RING, M D, *Secretary*

BOSTON SOCIETY OF ANESTHETISTS

The next meeting of the Boston Society of Anesthetists will be held in the Hotel Kenmore on Tuesday, June 12

The program

6 30—Dinner, main dining room

7 45—Business meeting, Colonial Room

8 00—Scientific program, Colonial Room Dr Will Sentman Taylor, professor of psychology at Smith

College, will talk on "Hypnotism Its Relation to General Medicine and to Anesthesia," and will induce hypnosis in a subject.

Physicians and medical students are invited

PHILIP D WOODBRIDGE, M D, *President*

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the office of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, June 12, 1934, at 12 noon This is the *second Tuesday* of June The meeting is being held at this time because the third week in June is Commencement Week, and it would be impossible for many to attend The speaker, June 12, will be Dr Tracy B Mallory, Instructor in Pathology at Harvard Medical School Chief of the Laboratory of Pathology and Bacteriology at the Massachusetts General Hospital His subject will be "The Pathology of Bronchial Asthma." All physicians are cordially invited to attend both lecture and luncheon

FAULKNER HOSPITAL CLINICAL MEETING

The final clinical meeting of the season will be held on Thursday, June 7, at 5 00 P M, at the hospital In addition to the usual clinical pathological conference Dr Edward L Young, Jr, who was scheduled to speak at the April meeting but was unable to do so will discuss "Some of the Difficulties of Gallbladder Diagnosis" All physicians who are interested are cordially invited

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

May 31—New England Medical Society will meet in the Evans Auditorium of the Massachusetts Memorial Hospitals 80 East Concord Street Boston at 8 15 P M

May 31 June 2—American Association for Thoracic Surgery A program of papers on thoracic surgery and allied subjects will be given on Thursday and Friday in Building C Amphitheatre at the Harvard Medical School On Saturday morning programs will be provided at the Massachusetts General Hospital the Peter Bent Brigham Hospital and the New England Deaconess Hospital on thoracic disease

June 4—New England Physical Therapy Society See notice elsewhere on this page

June 4—Worcester City Hospital Clinics See page 1137 issue of May 24

June 4—St. Vincent Hospital (Worcester) Clinics See page 1137 issue of May 24

June 5—Alumni Luncheon Massachusetts Alumni of the University of Maryland Medical School Baltimore Medical College College of Physicians and Surgeons Baltimore to be held at the Hotel Bancroft Worcester at 12 30 P M Reservations should be made through Dr W B Davidson (1917) 36 Pleasant Street Worcester

June 7—Faulkner Hospital Clinical Meeting See notice above

June 7, 8, 9—Annual Meeting of the American Association for the Study of Goltz will be held in Cleveland, Ohio For details of the program apply to Dr J R. Yung Terre Haute Ind

June 11—American Medical Golfing Association will meet at the Mayfield Country Club in Cleveland. For details see page 1090 issue of May 17

June 11 12—The American Proctologic Society will meet at the Hotel Cleveland Cleveland For information address the Secretary Frank G Runyon M D 1361 Perikomen Avenue Reading Pa

June 12—South End Medical Club See notice above

June 12—Boston Society of Anesthetists See page 1195

BOOK REVIEWS

External Diseases of the Eye By Donald T. Atkinson 704 pp Philadelphia Lea & Febiger \$7.00

Atkinson's *External Diseases of the Eye* a book of 674 pages and ample index, abundantly illustrated with 479 engravings will appeal to the general prac-

titioner who must refresh his memory about diseases which affect the anterior segment of the eyeball, and acquaint himself with the methods of treatment employed

Well taught and recent medical graduates will be disappointed to find so little about the bacteriology and histopathology of ocular lesions, about the valuable diagnostic information obtained from the anterior segment with the use of the corneal microscope and slit lamp, and about the supreme value of careful perimetry in following the progress of glaucoma of all sorts. The excellent arrangement of the subject matter, and the abundance of illustrations will make the book a useful one for orientation of the general practitioner

Hygiene of the Mind By Baron Ernst von Feuchtersleben Translated from the German by F. C. Sumner 150 pp New York The Macmillan Company \$1.25

This translation of a little book of essays by a German physician who was evidently intensely human in his attitude, though written a hundred years ago is of interest today to the doctor who views his patients as thinking living organisms, rather than as intricate machines. The Baron with prophetic insight saw beneath the surface of diseased segments into the minds which in the last analysis control those organs. His refreshingly individual philosophy is not far out of line with the thought of the most modern psychologists

Surgical Clinics of North America February, 1934 Volume 14 Number 1 Philadelphia Number 520 pp Philadelphia W. B. Saunders Company Paper \$12.00, Cloth, \$16.00

The principal feature of this number is a group of clinics on foreign bodies in the gastrointestinal tract by Shallow, Clerf and Manges. Foreign bodies in the esophagus or stomach can be removed endoscopically preferably with the aid of biplane fluoroscopy. Those which remain persistently lodged in the duodenum usually require operative removal while those that pass the duodenojejunal junction are usually passed naturally.

Ellison and McLaughlin present an analysis of thirty-two cases of postoperative pulmonary atelectasis with but three deaths. Although this report is from a bronchoscopic center, only two cases were subjected to bronchoscopy.

The meticulous care necessary in the treatment of chronic laryngeal stenosis is outlined by Jackson. Some cases can be satisfactorily dilated while others require careful plastic surgery.

The other clinics by leading surgeons of Philadelphia are well chosen to cover subjects that are sufficiently common to be of real practical value to the average surgeon.

The Massachusetts Medical Society

THE OBJECTIVES OF MEDICAL PROGRESS*

BY LINCOLN DAVIS, M D †

IT is well for doctors as for all mankind to pause occasionally in their pursuits and meditate upon the achievements of the past, the trends of the present, and aims for the future. It was doubtless with this purpose in mind that the founders of the Massachusetts Medical Society set apart an hour at each yearly meeting for an Annual Discourse. In attempting to prepare myself for the honorable duty which devolves upon me to-day, it has been a source of pleasure and instruction to review the discourses delivered before this Society from the first dissertation of 1804 down to the present time. Some of these addresses have been of a technical nature which, with the passing of the years and the advance of medical science, are valuable chiefly from an historical point of view, others, concerned with the broader aspects of the medical profession in relation to the community, are as vital to-day as at the time of delivery. In reviewing this mass of medical literature one cannot fail to be impressed with the wisdom, intelligence, and high character of the men who have represented the medical profession in Massachusetts. Some of these addresses have stood out as landmarks in the history of medicine, notably the Discourse on "Self-Limited Diseases" by Jacob Bigelow in 1835.

In 1860 Oliver Wendell Holmes' famous discourse "Currents and Counter-Currents in Medical Science" contained the oft-quoted passage consigning the materia medica to the bottom of the sea, in a biting satire against the prevailing overmedication of that day. The sensation which this caused is attested in the passage of a resolution by the Society shortly afterwards disclaiming responsibility for all past and future annual addresses.

A frequent subject of heated discussion in the past has concerned the inroads upon the regular profession by various irregular systems. To those who are to-day greatly disturbed by the recent activities of the chiropractors, I would commend the reading of Dr. Edward Reynolds'

and Dr. John Ware's discourses of nearly one hundred years ago. Dr. Reynolds said, "It would not be an unreasonable expectation that the extension of medical light to the community should abate the prevalence of medical folly, except for the fact that the fountains of human credulity, flowing on in undiminished fullness for six thousand years are evidently inexhaustible."

That the dangers of too much leisure were appreciated nearly a century prior to the New Deal is shown by the warning of Dr. George C. Shattuck in the Discourse of 1828. He said, "Increased luxury, diminished industry and the undue use of intoxicating liquors are impoverishing the fortunes, ruining the characters and destroying the lives of the immoral devotees to idleness and appetite."

Dr. John Homans, in his Discourse of 1844 on the "Character and Qualifications of the Good Physician", emphasized a quality which he himself possessed to a conspicuous degree and has handed down to his descendants of to-day. He said "Integrity is the great principle that should be at the bottom of the medical character."

A perusal of the delightful address of Dr. Thomas N. Stone of Wellfleet delivered in 1872 shows that the attitude of the profession toward our Legislature has not greatly changed in fifty years. "Every year", he said, "witnesses the birth of some new theory in medicine, some grand discovery in the laws of Nature, who in her old age seems as prolific of law as a Massachusetts Legislature." Speaking of the stern granitic ideas of the Puritan fathers he said, "They could in theology stand strong doctrine to the seventeenthly of a three hours sermon. In pathology they could bear bleeding, sweating and purging, in as large doses and as oft repeated. The beloved youth of whom Jefferson was wont to tell who died of a decline notwithstanding his attentive physician had bled him twenty six times was an effeminate son of the F's of Virginia, not a sturdy scion of the old Puritan stock."

Perhaps the most popular theme for annual discourses has been medical progress. This has been emphasized over and over again, and well

BOOK REVIEWS

External Diseases of the Eye By Donald T Atkinson 704 pp Philadelphia Lea & Febiger \$7.00

Atkinson's External Diseases of the Eye a book of 674 pages and ample index, abundantly illustrated with 479 engravings will appeal to the general prac-

titioner who must refresh his memory about diseases which affect the anterior segment of the eyeball, and acquaint himself with the methods of treatment employed.

Well taught and recent medical graduates will be disappointed to find so little about the bacteriology and histo-pathology of ocular lesions, about the valuable diagnostic information obtained from the anterior segment with the use of the corneal microscope and slit lamp, and about the supreme value of careful perimetry in following the progress of glaucoma of all sorts. The excellent arrangement of the subject matter, and the abundance of illustrations will make the book a useful one for orientation of the general practitioner.

Hygiene of the Mind By Baron Ernst von Feuchtersleben. Translated from the German by F C Sumner 150 pp New York The Macmillan Company \$1.25

This translation of a little book of essays by a German physician who was evidently intensely human in his attitude though written a hundred years ago, is of interest today to the doctor who views his patients as thinking living organisms rather than as intricate machines. The Baron with prophetic insight saw beneath the surface of diseased segments into the minds which, in the last analysis control those organs. His refreshingly individual philosophy is not far out of line with the thought of the most modern psychologists.

Surgical Clinics of North America February, 1934 Volume 14, Number 1 Philadelphia Number Clinic Year (February 1934 to December 1934) 226 pp Philadelphia W B Saunders Company Paper, \$12.00, Cloth, \$16.00

The principal feature of this number is a group of clinics on foreign bodies in the gastrointestinal tract by Shallow, Cierf and Manges. Foreign bodies in the esophagus or stomach can be removed endoscopically preferably with the aid of biplane fluoroscopy. Those which remain persistently lodged in the duodenum usually require operative removal while those that pass the duodenojejunal junction are usually passed naturally.

Ellison and McLaughlin present an analysis of thirty two cases of postoperative pulmonary atelectasis with but three deaths. Although this report is from a bronchoscopic center, only two cases were subjected to bronchoscopy.

The meticulous care necessary in the treatment of chronic laryngeal stenosis is outlined by Jackson. Some cases can be satisfactorily dilated while others require careful plastic surgery.

The other clinics by leading surgeons of Philadelphia are well chosen to cover subjects that are sufficiently common to be of real practical value to the average surgeon.

The Massachusetts Medical Society

THE OBJECTIVES OF MEDICAL PROGRESS*

BY LINCOLN DAVIS, M.D.†

IT is well for doctors as for all mankind to pause occasionally in their pursuits and meditate upon the achievements of the past, the trends of the present, and aims for the future. It was doubtless with this purpose in mind that the founders of the Massachusetts Medical Society set apart an hour at each yearly meeting for an Annual Discourse. In attempting to prepare myself for the honorable duty which devolves upon me to-day, it has been a source of pleasure and instruction to review the discourses delivered before this Society from the first dissertation of 1804 down to the present time. Some of these addresses have been of a technical nature which, with the passing of the years and the advance of medical science, are valuable chiefly from an historical point of view, others, concerned with the broader aspects of the medical profession in relation to the community, are as vital to-day as at the time of delivery. In reviewing this mass of medical literature one cannot fail to be impressed with the wisdom, intelligence, and high character of the men who have represented the medical profession in Massachusetts. Some of these addresses have stood out as landmarks in the history of medicine, notably the Discourse on "Self-Limited Diseases" by Jacob Bigelow in 1835.

In 1860 Oliver Wendell Holmes' famous discourse "Currents and Counter-Currents in Medical Science" contained the oft-quoted passage consigning the *materia medica* to the bottom of the sea, in a biting satire against the prevailing overmedication of that day. The sensation which this caused is attested in the passage of a resolution by the Society shortly afterwards disclaiming responsibility for all past and future annual addresses.

A frequent subject of heated discussion in the past has concerned the inroads upon the regular profession by various irregular systems. To those who are to-day greatly disturbed by the recent activities of the chiropractors, I would commend the reading of Dr. Edward Reynolds'

and Dr. John Ware's discourses of nearly one hundred years ago. Dr. Reynolds said, "It would not be an unreasonable expectation that the extension of medical light to the community should abate the prevalence of medical folly except for the fact that the fountains of human credulity, flowing on in undiminished fullness for six thousand years are evidently inexhaustible."

That the dangers of too much leisure were appreciated nearly a century prior to the New Deal is shown by the warning of Dr. George C. Shattuck in the Discourse of 1828. He said, "Increased luxury diminished industry and the undue use of intoxicating liquors are impoverishing the fortunes, ruining the characters and destroying the lives of the immoral devotees to idleness and appetite."

Dr. John Homans, in his Discourse of 1844 on the "Character and Qualifications of the Good Physician", emphasized a quality which he himself possessed to a conspicuous degree and has handed down to his descendants of to-day. He said "Integrity is the great principle that should be at the bottom of the medical character."

A perusal of the delightful address of Dr. Thomas N. Stone of Wellfleet delivered in 1872 shows that the attitude of the profession toward our Legislature has not greatly changed in fifty years. "Every year", he said, "witnesses the birth of some new theory in medicine, some grand discovery in the laws of Nature, who in her old age seems as prolific of law as a Massachusetts Legislature." Speaking of the stern granitic ideas of the Puritan fathers he said, "They could in theology stand strong doctrine to the seventeenthly of a three hours sermon. In pathology they could bear bleeding sweating and purging, in as large doses and as oft repeated. The beloved youth of whom Jefferson was wont to tell who died of a decline notwithstanding his attentive physician had bled him twenty-six times was an effeminate son of the F. F.'s of Virginia, not a sturdy scion of the old Puritan stock."

Perhaps the most popular theme for annual discourses has been medical progress. This has been emphasized over and over again and well

*The Annual Discourse delivered at the Annual Meeting of the Massachusetts Medical Society Worcester June 6, 1934.

†Davis—President Boston Medical Library. For record and address of author see "This Week's Issue" page 1-34.

may it have been so, for the progress has been truly remarkable. In some cases, dazzled by the brilliant achievements of their age, speakers have been lured into expressions of conviction that the ultimate had been reached. How often have such conclusions been confounded in the light of history!

The very pinnacle of medical progress would seem to have been attained in 1817 when the author of the Annual Discourse of that year in speaking of modern physiologists said, "They have so minutely investigated, and so perspicuously illustrated every topic connected with their profession that all pretensions to originality, and every claim to novelty are denied to their successors."

Dr Josiah Bartlett in his address of 1810 said, "It has been remarked that more professional knowledge is at this time attainable in a single season, than was known to Hippocrates, Galen and their successors till the beginning of the eighteenth century. A case of fistula in ano, now considered as a simple disease, and often cured by our youngest practitioners, was in 1686, nearly seventy years after the settlement of Massachusetts so formidable and dangerous, that Felix a surgeon and Fagon a consulting physician were rewarded with forty thousand dollars for a successful operation on Lewis the Fourteenth of France, in consequence of which a national thanksgiving was religiously observed." This passage might seem to indicate a retrogressive rather than a progressive trend not only in pecuniary rewards since 1686, but also in the surgical treatment of fistula in ano since 1810.

That medical progress should be measured not solely by an enumeration of the obstacles overcome but by a survey of the advancement toward definite objectives, was emphasized by Dr George C. Shattuck the second, who said in 1866 "no one can deny or doubt that we have made and are making great advances, but the horizon opens before us as we go on, and the extent of the field becomes even more apparent than our progress."

For a graphic illustration of this same point of view I must again turn to Oliver Wendell Holmes. He said, "Sir Edward Parry and his party were going straight towards the pole, in one of their Arctic expeditions, travelling at the rate of ten miles a day. But the ice over which they travelled was drifting straight towards the equator at the rate of twelve miles a day, and yet no man among them would have known that he was travelling two miles a day backward, unless he had lifted his eyes from the track in which he was plodding."

* * * *

With these warnings fresh in mind I will venture a few guarded comments on the alluring

subject of medical progress since the days of our forefathers.

A striking feature of Colonial medicine was the participation by the clergy in the care of the sick. As Dr Henry Viets tells us in his History of Medicine in Massachusetts, "the ministers were expert in phlebotomy, and they were wont to bleed and pray in all severe cases." This was merely the cropping out in America of the very widespread association of religion with the healing art which has prevailed in all primitive cultures. The early Greek temple medicine, the Asclepieia, exemplified this trait. It flourished in Egypt in still earlier times. In Europe in the Middle Ages the monasteries preceded the hospitals in the care of the sick.

Since then specialization in medicine has carried us very far indeed from this primitive blending of the functions of two related professions, so far in fact that there are now distinct signs above the horizon of the completion of a cycle with return to a recognition of the mutual benefits of peace of mind and of body. Dr Walter Cannon in his Discourse of 1928, emphasizing the emotional elements in disease, laid a scientific foundation for the participation by the regular profession in a field which had hitherto been largely abandoned both by the medical profession and the clergy to faith healers and cultists.

The stoical fortitude displayed by our forefathers in withstanding the three hour sermons, and the bleeding, sweating and purging in corresponding doses so vividly portrayed by Dr Stone was not peculiar to New England. The heroic medical dosage of those Colonial days was merely the transplantation to these shores of the accepted principles of the medical art of the mother country.

The state of medical practice in England at the end of the seventeenth century is well illustrated by the amazing account of the fatal illness of Charles II in "The Mysteries of History" by C. J. S. Thompson. The King was treated by the foremost physicians of England, fourteen in number in constant consultation. The diagnosis was never made, not even at the autopsy. Emetics, purges, clysters, bloodletting from arm and jugular, cupping, blistering of head and feet, scarification, secret elixirs, spirits of human skull and bezoar stones were employed without avail, fifty eight different drugs in all were administered. The unfortunate King finally succumbed after six days, the irony of his famous apology for taking such an unconscionable time a dying seems obvious.

The contrast is striking between the status of medicine of this period and the status of literature and the arts, which had already reached a stage of development which has remained unsurpassed if not unequalled. The physical sci-

ences on the other hand have made amazing progress since those days. Medical science has gone far since the days of Charles II, somewhat of a laggard at first it has within the last half century made prodigious progress. The causal factor of one disease after another has been discovered and in many cases, especially in the bacterial diseases, their control secured. No longer do great epidemic scourges such as plague, smallpox, leprosy, cholera, yellow fever, dysentery, malaria, typhoid, typhus, and diphtheria decimate vast numbers of the people. Of the great infectious epidemics, influenza alone still rages at intervals unchecked through the teeming inhabitants of the civilized world. Equal progress has been made in controlling many of the hitherto obscure constitutional and deficiency diseases, such as diabetes, rickets, pernicious anemia, and scurvy. The triumphs of modern surgery have been even more spectacular, it is unnecessary to rehearse them before this audience. Though we may well be proud of these accomplishments of medical and surgical science in banishing or controlling most of the terrible epidemic diseases of the past and mechanically readjusting many of the derangements of the human frame, the race is still sorely afflicted with ills of body and mind. As one malady is conquered and laid low, another seems to spring up in its place to attack mortal man.

Appendicitis, the pathology of which was first fully elucidated by Reginald Fitz in 1886, has undoubtedly existed from the earliest times. Yet it is only in the modern era that it has become such a factor in morbidity and mortality statistics. Infantile paralysis, which strikes such terror into the hearts of parents to-day, has been traced back to the earliest historical period. In the past it has been obscured by the greater ravages of the more deadly epidemics for it is only after the elimination of the greater terrors that the lesser ones assume important proportions.

Reports of new diseases such as encephalitis lethargica, tularemia, granuloma inguinale, agranulocytic angina, epidermophytosis, etc., appear from time to time in the medical journals. These are probably not new diseases but pathological conditions of long standing which have been recognized and classified for the first time.

It may well be, however, that new bacterial diseases are actually evolving. Why should not bacteria undergo evolution as well as the higher plants and animals? Opportunity for the development of sports and mutations might well occur in organisms of such short life cycle. Kirtley Mather tells us to be sure that in the cliffs of the coast of Wales of the Cambrian period there are fossils of brachiopods indistinguishable in form and structure from their

descendants living to day at the foot of these cliffs after five hundred million years. These, however, are striking exceptions to the well-nigh universal law of organic evolution. Are bacteria like brachiopods, or are there processes of evolution going on whereby these parasites of human woe in their fierce struggle with the medical profession for existence are developing by means of hard shell spores, or invisibility or shrinkage in size, ways of withstanding the autoclave, or eluding the microscope of the bacteriologist and epidemiologist? This is an interesting speculation to which recent investigations of pleo antigenic bacteria seem to lend scientific plausibility. I will venture just one prophecy that the time will never come when there will be an Alexander the Great in medicine with occasion to weep that there are no more diseases to conquer.

* * * *

In the troubled stream of medical progress with its many windings, countercurrents, shoals, rapids and occasional stagnant pools, is it possible to determine the direction of the main trend? There is a confusion of conflicting views and opinions. Dire warnings of impending disaster to the profession have been freely uttered from diverse sources of late.

It was but a short time ago that the word efficiency was upon everybody's lips, efficiency experts were abroad in the land making surveys of every conceivable form of human effort. The medical profession did not escape their scrutiny. Some of the methods of the doctors and hospitals seemed crude, primitive, and wasteful, compared with the smooth working of big industrial establishments. Big business was worshipped as a god in those days. We doctors were told that we must adopt the efficient methods of big business, if we were to survive in the fierce struggle for economic existence.

Hospitals were especially criticized as extravagant in their administration and wasteful of human effort. I have seen, a few years back, an industrial efficiency expert in the operating amphitheatre of one of our large hospitals observing operations. His comments were to the effect that he observed much wasted motion. Doubtless true. No two surgical cases are exactly alike. The vermiform appendix has many hiding places, the sac of a hernia may likewise be exceedingly elusive. Care, patience, and constant vigilance, are the price of safety in operating. It is better to waste motion than blood or life. The avoidance of infection is cheap at the price of infinite pains and seeming fussiness. In other words, there is a vital human element in the relations of the doctor to the patient that cannot be standardized like the laying of bricks or the assembly of automobiles. Fortunately the danger of the adoption of the

factory-belt system in hospitals seems to have passed for the present

There is much to admire and respect in the achievements of the great industrial organizations of America. Their prosperity has meant prosperity for the people and vice versa. Their leaders have been in the main broad-visioned, courageous, progressive, and often extremely philanthropic men. It is perhaps too much to expect them to be primarily altruists or sociologists. I am well aware that much of the medical research, of whose products we are so proud, emanates from foundations established by the generosity of wise leaders of the business world. Our medical schools and hospitals also owe a debt of gratitude to many such enlightened philanthropists. The best results, however, have been obtained in those institutions whose policies have been wisely left to experts in the field and not dictated from outside. Business naturally comes first for business men. Big business is inclined to look upon homo sapiens primarily as a consumer of material goods. With ever-expanding production big business has employed the wiles of the super-salesman and advertiser to force the absorption of an ever-increasing volume of automobiles and apartments, houses and house furnishings, refrigerators and radios, clothes and cosmetics, cigarettes, candies and chewing gum, until the saturation point present and future is attained. Homo and mulier sapientes less sapient than the name implies responded eagerly to the alluring program spread before them, cheerfully mortgaging their goods and their future in the mad pursuit of so-called happiness. Happiness as President Lawrence Lowell has so emphatically stated, contrary to the preamble of the Declaration of Independence, is not to be won by pursuit but is a by-product of earnest endeavor along other lines.

As a result of the orgy of spending and lending, borrowing and mortgaging in the pursuit of false happiness the nation has been brought almost to the verge of ruin. In the train of the financial and social shipwreck there has been an aftermath of mental and physical distress which has had its medical repercussions in worry, ill health, nervous breakdown, insanity and suicide.

To day we hear less of the inefficiency of medicine, there is not so much criticism of the quality of medical care as of its cost. Big business rudely jarred from its former pedestal is fully occupied with its own problems but a host of social economists have come forward raising their voices in a laudable attempt to restore order in a disordered land. In the days of prosperity the cost of medical care was not a pressing problem. To day it has suddenly become a most vital one. It seems evident that

neither organized private charity, nor the charitable service of private physicians, which has so long been a part of the doctors' code, can be reasonably expected to carry the increased load of the indigent sick incident to unemployment and diminished wages on the part of a large proportion of the population. Many and diverse plans have been offered for the solution of this problem. National, state and community medicine, health and sickness insurance, group practice, hospital and university extension and other schemes have been advocated. There are advantages and dangers in these programs, varying local conditions require varying remedies. I have no solution to offer and can only observe that no radical or sweeping immediate change seems either necessary or wise. I agree with those who advocate a policy of carefully observed experimentation on a small scale, modifying methods according to varying conditions in different sections of the country. This is not a policy of "laissez faire", call it trial and error if you like, it is the scientific method, the process by which the medical progress of the past which we have been recording with justifiable pride has been attained. Accurate records of results should lead to an evolutionary development of those means best adapted to the needs. The situation is difficult and complicated. The best medical care depends on a personal relation between doctor and patient based on mutual confidence and harmony which it is difficult to secure in large cooperative efforts. We should be slow to discard the methods which in the past have on the whole given such good results until we are sure that newer ones are better.

Over and over again countless speakers in and out of the profession have emphasized the impending doom of the general practitioner submerged by the rising tide of modern specialization. To some of us on the contrary it has seemed that this very increase of specialism has made the position of the general practitioner all the more necessary. Medical practice has not advanced along a single broad highway. There are many diverging avenues and roads, some blind alleys, many branching paths and unfrequented trails. Signposts to be sure are not lacking along the way, but the multiplicity of conflicting directions bewilders the wandering patient seeking a haven of relief from his ills. If wise he will employ a trustworthy and experienced guide.

An eloquent plea for the family medical adviser was most ably presented by my immediate predecessor in 1933, and I imagine we all agree with him as to the desirability of establishing such a practitioner as he pictured. The prime requisite however, it seems to me, is to make sure of the family to be advised. To

some of us it appears that American family life is showing serious signs of disintegration. The entrance of women into business and industry, the prevalence of divorce, the tendency of human beings to herd together in large cities in monstrous apartments and tenements are all tending to restrict family life in America. The threat to family life is not confined to the United States by any means. It is undergoing its greatest perils at the hands of Soviet experimentation in Russia, the results of which are awaited with interest by the other nations of the globe. From the earliest period of recorded history and before, the family has been the foundation of human society. To be sure there have been cultures scattered among primitive peoples founded on other bases, such as promiscuity and group marriage, but the peoples that have showed progress and made history have without exception maintained the family relation. Is the present concern about the preservation of the family occasioned merely by a trifling and temporary oscillation in the broad onward sweep of civilization, or is there a distinct deviation of trend from the broad pathway of the past? Who can tell?

Dr. W. M. Wheeler in a recent symposium on "Biological and Society" before the American Society for the Advancement of Science contrasted the societies of termites and hymenoptera with vertebrate and mammalian societies, the former being characterized by a communal association marked by harmony and cooperation and dominated by female leadership. Vertebrate and mammalian societies, and included in these is human society, have been harassed by what he calls the "problem of the male." Male leadership has resulted in strife, disharmony and constant change and hence progress. The hymenoptera date back to geologic periods far antedating man. Furthermore, they go through thirty generations to man's one. Hence their society is a far more experienced one than ours. The query naturally arises, may these tendencies away from family life on the part of modern man and I should not omit woman, which are causing some of us such great distress denote a social evolutionary trend toward the civilization of the ant and the termite? If so, very radical and to many of us unwelcome biological changes of structure and function will be necessitated to attain the highly perfected and coordinated society of these insects. It is true that already artificial means such as sterilization of the unfit, have been adopted by man to meet certain threatening conditions, a further extension of this procedure might conceivably provide a class of sexless workers but I have not yet heard any active propaganda by man for female domination or, by woman for the prodigious female fecundity of the arthropods.

After all these insect societies may not be so pleasant and harmonious as they appear

No psychoanalyst has informed us of their emotional conflicts, their egos, urges, and subconscious states. We do know that they engage in war and harbor the institution of slavery, two indications of disharmony, one of which civilized man has succeeded in eliminating after an age-long struggle.

Let us return to more immediate concerns. The very foundation of American democracy including the practice of family medicine depends on the preservation of family life. Each family occupying and owning its own home with a plot of land is an ideal, which was nearly realized in New England at the time of the founding of the republic and is no less desirable now. Every head of a family should feel that he has a stake however small in the country. Nothing gives such a sense of responsibility and stability as the ownership of land. At the present time there is a widespread appreciation of this, and strong efforts are being made by some socially-minded leaders for the decentralization of industry, whereby men may live on small farms and work part time in small factories. This seems a promising experiment. With the automobile, improved roads, electricity, and the radio, the former isolation and drudgery of country life has been largely eliminated, and there has been a distinct and salutary movement back to the land which should be encouraged in every way.

The dangers moral and physical of a huge floating population aggregated in the great cities moving about from one wretched tenement to another in search of work or support, have been amply demonstrated in the last few years and is well appreciated by the physician. The medical profession then if it seriously wishes to establish and maintain the family, medical adviser must take part in the great social movement to safeguard the family itself.

With the progress of medical science and art the sum of medical knowledge which students must acquire becomes increasingly greater and now assumes appalling proportions in the minds of the elder generation. Fortunately, the younger generation seems to view the situation with a fair degree of equanimity and confidence. Each generation must learn more than its predecessor, not ignoring the discoveries and errors of the past, it must keep abreast with its own advances. The human brain seems to have been capable of absorbing this increased load of knowledge so far and the saturation point fortunately does not seem to have been reached for the higher intellects at least. In every generation there still are a few exceptional individuals, geniuses they are called, who are even capable of adding original contributions to the sum of previous knowledge.

Human offspring however are born into the world to-day as ignorant as they were six thousand years ago at the dawn of the historical era.

An increased capacity for acquiring knowledge may be inherited, but the knowledge itself has to be imparted, demonstrated, or hammered in, by a slow and painful process

It is a source of frequent and perhaps sophomoric argument as to whether there has been actual advance in human intellectual achievement since the days of the Greeks. However debatable this question may be as regards attainments in literature and the arts, progress has been undeniable in the sciences, and especially in medical science. This does not necessarily imply an evolutionary advance in human brain power. The time interval has been comparatively short for evolutionary changes as judged by the time scale of man's ascent from simian stock. The advance in scientific knowledge has been gained bit by bit, and through generation after generation, by observation and experiment aided by the discovery and perfection of instruments of precision which have enormously extended the field of observation, so that the human brain to day has tools to work with which were denied to its predecessors. There is no question that the educated man of to-day is required to retain a mental impression of a mass of facts and figures, words and formulae, which like entropy are ever-increasing and never diminishing with which the minds of the Grecian youth of the time of Aristotle were comparatively unencumbered. To continue the scientific advance and arrive nearer the goal of ultimate knowledge, each generation must hand on to the next the achievements and truths obtained at the cost of so much labor and suffering hence in the medical profession our interest in, and solicitude for, those agencies engaged in the preservation, extension and promulgation of medical knowledge, medical schools, hospitals, libraries, health boards, and medical societies

Those of us who have served on the examining boards of large hospitals and have had the opportunity of seeing large numbers of young medical graduates coming up for internship cannot fail to have been impressed with the capabilities of these young men, their mental activity, intelligence, and earnestness. It is a never-ceasing source of wonder to observe the adaptability of our surgical internes. They come to the hospital unskilled in the technique of a highly technical profession. After an eighteen-months' internship and a year or two of experience as resident, the best of them master the manual part of surgery to such a degree, that they equal and often excel the skill of their teachers who have spent a lifetime in the operating room. This phenomenon which is perhaps somewhat humbling to the pride of the visiting staff is for the good of the art. Judgment, poise, and discernment, are acquired somewhat more

slowly. There surely is no ground for anxiety on the score of the new material which is coming into our profession at least in this locality and in the larger hospitals. I believe the same to be true elsewhere as well.

A few words in praise of the older men in the profession, the practitioners of medicine and surgery, may be allowed as the privilege of one no longer an active participant in practice. With a few striking exceptions I firmly believe that the members of our profession have nobly upheld the principle of integrity of character emphasized by Dr. John Homans so many years ago. Taken by and large they have also upheld the best traditions of family life. Realizing a true sense of values they have led simple, unselfish, busy and happy lives free from the taint of commercialism and hypocrisy. They are almost universally lovers of nature and the great outdoors. Music, art, literature and sport have been abundantly cultivated in their spare hours. High-minded, humane and altruistic, no body of men is more worthy of respect and consideration. They have conquered many dragons in the past for the benefit of humanity. Others of a different breed now lie across their path.

* * * *

The triumphs of modern medicine and surgery have indeed been great. It would be both unnecessary and tedious to this audience to rehearse them in greater detail. How far then have we progressed toward our true objectives?

These objectives are generally stated to be the prolongation of life, the relief of suffering, the prevention and control of disease, and the promotion of the health and well-being of man.

As to the prolongation of life, reliable statistics conclusively show that life expectancy has been very considerably extended during the last century. One hundred years ago the average expectation of life at birth was about forty years. The latest statistics show the amazing figure of over sixty years for average life expectancy at birth. This extraordinary advance has been accomplished largely by a decrease in the mortality rate of infants and children. The mortality rate of adults of middle age and beyond has not been appreciably diminished in the last fifty years. It would be unreasonable to expect that the range of life expectancy should increase in the future at the rate which it has in the last hundred years. As long as man is mortal, disease and death must come. The effort to extend the span of life must inevitably come into ultimate conflict with the second objective, the alleviation of suffering, unless or until that ideal of the natural death so earnestly expounded by Metchnikoff should finally be attained. In this connection I feel impelled to express my personal conviction that the pro-

longation of life by highly artificial means at the expense of suffering, in the last stages of fatal disease, is neither sensible nor humane.

The relief of suffering, our second objective, although very far from being attained has been immeasurably advanced: anesthesia, analgesia, nerve blocking, the aseptic treatment of wounds, expert nursing, and countless new inventions in technique and instrumentation have contributed to this end.

Our third objective, the prevention and control of disease, has already been commented upon. The record is a brilliant one in which medical science and art drawing on the researches of many allied sciences together with the coöperation of an enlightened people have accomplished much with high hopes of an even more brilliant future.

Much still remains to be done. The uncontrolled incidence of many infections, especially those of the respiratory tract including the common cold, influenza and pneumonia is a challenge to the profession of to-day. Cancer and other malignant tumors are perhaps the greatest scourges of modern times. The degenerative diseases of the vascular system seem to be definitely on the increase. Arthritis is as prevalent and crippling as ever. Nervous instability, mental derangements, idiosyncrasy and insanity are increasing problems.

Our final objective, the promotion of the health and well-being of man is one of vast scope. The promotion of health involves not only the prevention and control of disease but the maintenance of the state of being well physically and mentally. The promotion of well-being involves in turn more than the maintenance of good health. The words "being well" when transposed to "well-being" have acquired a broader meaning denoting general welfare including material and spiritual attributes of life which transcend the scope of medicine.

Much has been done for the promotion of the health and well-being of man in preventive medicine, surgery and dentistry, through the instrumentality of many organizations, national, state and local, engaged in promoting public health, sanitation, hygiene, physical, social and mental, accident prevention, social service, dietetics, health examinations and public instruction. Much more remains to be done and "the extent of the field becomes even more apparent than our progress." The problems involved are the most serious and difficult which concern the medical profession to-day. It is not only the medical profession which is concerned, but the whole body politic. It will require the intelligent cooperative efforts of our governing bodies, and of all forward-looking agencies, professions and individuals, to achieve real progress toward this objective.

The strain of present-day life is taking a heavy toll from those caught in the irresistible tide of what is called our advancing civilization. Not only does it exact its penalties on the nervous, circulatory and digestive systems, but the mechanized civilization of to-day is destroying its thousands and maiming its hundreds of thousands by direct external violence.

It has been the proud boast of man that in building up his civilization he has overcome the forces of nature, but in the process he has raised up mechanical monsters of destruction far more perilous than all the plagues of the past.

To the physician earnestly struggling to reduce the morbidity and mortality of disease the attitude of the public and the governing powers often seems incomprehensibly blind, if not callous. It is disheartening to say the least to those who have dedicated their lives to war on cancer, tuberculosis, and infectious disease to realize how little value the community apparently sets on human life as manifested by its complacency toward the staggering sum of fatalities from accident, homicide, and suicide.

The widespread participation in all forms of insurance by the American people is doubtless commendable. It spreads the financial burden resulting from casualties, which might be crushing to an individual, over such a large number of policyholders as to seem nominal. By the same token it tends to dull the moral sense of responsibility of the reckless toward accidents. There is a state of mind altogether too prevalent which might be expressed in the vernacular: the company pays the damages, step on it. It is the community that pays in the long run and is paying grievously dear.

The insurance companies of course are well aware of the situation and have made commendable efforts to correct it. Corrective measures to be effective, however, must come from other sources.

Figures compiled by one of the large national insurance companies show that in the year 1933, there were 29,900 deaths in the United States as the result of automobile accidents, 4,850 of these were among children. Over 850,000 persons were injured, 139,000 of these were children under 14 years of age. In the last ten years over 273,000 persons have been killed by automobiles. In the last four years there have been nearly four million injured. These figures far overshadow the casualties incurred by the American Expeditionary Forces in the Great War. The official war figures are 36,694 killed in action and 224,089 wounded of whom 13,691 died of wounds. We are all well aware of the cost to the nation of the disabilities resulting from the World War. Estimates of the cost of the nearly four million injuries resulting from automobile accidents in the last four years stagger

the imagination. It is estimated that the cost of industrial injuries alone is over five billion dollars annually.

The mortality statistics of the census bureau for the registration area of Continental United States for the year 1929, the last year for which full official figures have been published, show over 94,000 deaths from accidents, over 16,000 suicides, and just under 10,000 homicides, a total of 120,000 violent deaths. These three forms of violent death together account for more victims than any single cause in the international classification of causes of death with the sole exception of heart disease, which was recorded as the cause of 245,244 deaths. Next comes cancer with 111,000, pneumonia and nephritis each 106,000, and so on down the list. For those in the active period of life, from twenty to forty-five years of age, deaths by violence exceed any other cause of death. It is significant that, of the 1,386,363 inhabitants of the United States who died in 1929, only 12,319 were recorded as dying of old age in that hectic year. What of the great epidemic scourges of the past? In 1929, 151 persons died of smallpox, nineteen of typhus, none of plague, none of yellow fever, none of cholera.

Of all the forms of death it would seem that violent and accidental death should be the most preventable except those resulting from the uncontrollable convulsions of nature such as storms on land and sea, earthquakes, floods, landslides, lightning, sunstroke, etc., which in this fortunate land have been factors of relatively minor importance. The blame is not to be laid on nature but on man.

The disabilities and deaths resulting from accident and depravity may not be considered to be strictly within the province of the medical profession. It is, however, the medical profession which is called on for the treatment of the victims, and with the same altruism which our profession has demonstrated in the prevention of disease we should join in the attack upon these modern scourges at their source. A very notable improvement in the rate of fatalities and accidents in industry has already resulted from the cooperative efforts of government, industry, and labor, with the medical profession. This is, however, but a part of the problem and the smaller part.

The profession needs to be aroused to the full implications of our objective of promoting the well-being of man. The problem involves grave questions of sociology, economics, and gov-

ernment, which are beyond our control, it is true, but the united medical profession should and would have an enormous influence for good if exerted in the right direction. To no one are the varying traits of weakness and nobility in human nature more deeply revealed than to the physician. He is by training and instinct sympathetic and understanding. He is well aware of the crying need in domestic life of the cultivation of those simple basic virtues upon which the maintenance of the home and family depend. He is equally well aware of the crying need of character, integrity and intelligence in public affairs. What body of citizens is better qualified to help in promoting these by precept and example?

Many organizations and individuals outside the medical profession are actively engaged upon these problems at the present moment. Many individuals and organizations within the medical profession and among them members of this Society have for many years waged a valiant battle for the betterment of social and industrial conditions affecting the health and well being of the community.

The profession as a whole, however, is apathetic, reluctant to venture beyond what seems its legitimate field, but as Dr. Shattuck said so many years ago "the horizon opens before us as we go on."

Without relaxing for a moment our efforts along the lines of past endeavor, for the frontiers against disease so hardly won must be maintained and extended, we must at the same time take the offensive against an even more insidious foe infiltrating the fabric of our social welfare.

The active participation by the medical profession in civic, economic and sociological matters affecting the well-being of the people is, I believe, sorely needed to day to avert a social cataclysm threatening the very life of the nation.

We must, like Sir Edward Parry's Arctic party, raise our eyes from the track along which we are plodding to above the horizon if we would measure the progress toward our true objectives.

I would not advocate a return to the teleological views of Galen, but a teleology of aim and effort is as essential in medicine as in religion of which it might be considered a part.

The occasion is pressing, the capabilities are at hand, may neither the vision nor the will be found wanting.

A CASE OF POSTENCEPHALITIC PARKINSON'S DISEASE
TREATED BY TOTAL THYROIDECTOMY*

BY ABRAHAM MYERSON, M.D.,† AND DAVID D. BERLIN, M.D.‡

THE rationale which prompted one of us (Abraham Myerson) to select a case of Parkinson's disease for total thyroidectomy is as follows

1 In active untreated cases of Parkinson's disease the metabolism is increased. Thus in a very severe case who was deprived of sedative medication for a week, the metabolism rose to +60 per cent. In several other cases the metabolism has ranged between +15 and +40. When these same cases are given large doses of stramonium or hyoscyne with some control of tremulous muscular activity, the metabolism drops. These cases will be cited, together with other facts in a detailed manner, in a later paper.

2 The drugs that are in any way successful in ameliorating the condition of patients with Parkinson's disease lower metabolism.

3 These facts together with the belief that the normal thyroid activation is too great for an organism with defective neuromic links lead to the hypothesis that if the thyroid were totally removed and the patient allowed to become myxedematous, the myxedema could be controlled and the symptoms would be ameliorated in much the same way that reducing the speed of an engine lessens shaking and rattle in a light or defective machine.

The later facts showed that this rationale of approach is not entirely correct. Nevertheless, the results of operation were quite striking.

CASE HISTORY

Estelle C. aged 32 married had encephalitis at the age of nineteen. In the next two years the patient was quite sleepy, weak and depressed. This condition persisted moderately until about twelve years ago when she began to notice shaking of the right leg. Gradually this shaking spread to all limbs, face and tongue. The face became stolid, and the patient presented a characteristic Parkinson's syndrome. Her baby was born in 1927. Her symptoms increased. Her condition grew worse despite the varied types of treatment she underwent and for two months before it was decided to perform a thyroidectomy upon her she had become bedridden. The tremor was as marked as any case we have noted. The churning of the jaws was so great that the saliva became very foamy. She could not feed herself and her speech was almost indistinguishable. At this time she was receiving eight hypodermic injections of 1/50 hyoscyne each day together with varying, but large, doses of luminal, amylal and other sedatives.

With grateful acknowledgment to the Greater Boston Bickur Cholim Hospital and the Beth Israel Hospital whose cooperation made this procedure possible and to the patient who fully and freely gave her consent.

†Myerson—Professor of Neurology, Tufts College Medical School. Berlin—Assistant Professor of Anatomy, Tufts College Medical School. For records and addresses of authors see "This Week's Issue" page 1334.

She had received during the period of her illness from various neurologists hyoscyne, stramonium, harmin, atropin, parathyroid gland, calcium lactate, and belladonna. It is noteworthy that 3 gr of stramonium leaves three times a day had no effect. Sterile milk was also employed in the latter part of 1930. Typhoid vaccine was tried for a moderately prolonged period of time. Thus, in summarizing the treatment, all forms had been used, and even with the most massive doses of hyoscyne and other drugs, she had become bedridden and her tremor and rigidity were extreme, the tremor being more noticeable, however, than the rigidity.

She entered the Greater Boston Bickur Cholim Hospital on June 5, 1929. She was sent to the Beth Israel Hospital on December 5, 1933 where a total ablation of her thyroid was done without incident by Dr. David D. Berlin. Prior to the operation her metabolism was -29. This we ascribed to the enormous doses of hyoscyne which she was receiving.

No noticeable improvement occurred during the first two weeks. In fact, when she left the hospital her condition was probably somewhat worse than before the operation. About the third week it was noted that the patient's condition was improving. Gradually as she approached myxedema, manifested by harshness of the skin and a dropping metabolism which reached -35, it became possible to control her condition with much less hyoscyne than before. Some time in the early part of February 1934 the patient was able to get up out of bed, walk, raise her hands and hold them out stretched with but little tremor. There was some definite tremor around the month. She could be kept in this condition with three doses of hyoscyne a day together with a small dose of luminal. Prior to operation she had complained of pain in her ankles and feet. This pain became the most troublesome of her symptoms.

On March 21, 1934 the note states: patient walks with a slight drag of the legs and with a typical Parkinsonian facies and lack of associated movements. Her speech is clear although the voice is weak. There is no noticeable tremor of the face. The tongue protrudes straight, is red, and without noticeable tremor. There is marked plastic rigidity of the neck. The patient can feed herself. When she raises her arms they are held quite steady. Her grip is fairly firm. There is no swing of tremor to the opposite side when either hand is used. Although movements of the hands set up an associated tremor which is slight of the mouth. Her arms are not spastic. The patient herself feels very much better. She does not fall asleep so frequently as formerly and she is very grateful for the results.

THE EFFECT OF ELIMINATING THE HYOSCYNE

The hyoscyne was not administered for two days. During this period the patient became markedly worse and in fact, reached her pre-operative stage. She became so tremulous that she could not use her hands. Her speech became very indistinct and the churning of the saliva into foam recurred. When she was put back on hyoscyne which is now being administered in two doses of 1/50 gr, the symptoms became immediately ameliorated to the point where she is now ambulatory.

the imagination. It is estimated that the cost of industrial injuries alone is over five billion dollars annually.

The mortality statistics of the census bureau for the registration area of Continental United States for the year 1929, the last year for which full official figures have been published, show over 94,000 deaths from accidents, over 16,000 suicides, and just under 10,000 homicides, a total of 120,000 violent deaths. These three forms of violent death together account for more victims than any single cause in the international classification of causes of death with the sole exception of heart disease, which was recorded as the cause of 245,244 deaths. Next comes cancer with 111,000 pneumonia and nephritis each 106,000, and so on down the list. For those in the active period of life, from twenty to forty-five years of age, deaths by violence exceed any other cause of death. It is significant that, of the 1,386,363 inhabitants of the United States who died in 1929 only 12,319 were recorded as dying of old age in that hectic year. What of the great epidemic scourges of the past? In 1929, 151 persons died of smallpox, nineteen of typhus, none of plague, none of yellow fever, none of cholera.

Of all the forms of death it would seem that violent and accidental death should be the most preventable except those resulting from the uncontrollable convulsions of nature such as storms on land and sea, earthquakes, floods, landslides, lightning, sunstroke, etc., which in this fortunate land have been factors of relatively minor importance. The blame is not to be laid on nature but on man.

The disabilities and deaths resulting from accident and depravity may not be considered to be strictly within the province of the medical profession. It is, however, the medical profession which is called on for the treatment of the victims and with the same altruism which our profession has demonstrated in the prevention of disease we should join in the attack upon these modern scourges at their source. This is, however, but a part of the problem and the smaller part.

The profession needs to be aroused to the full implications of our objective of promoting the well-being of man. The problem involves grave questions of sociology, economics and gov-

ernment, which are beyond our control, it is true, but the united medical profession should and would have an enormous influence for good if exerted in the right direction. To no one are the varying traits of weakness and nobility in human nature more deeply revealed than to the physician. He is by training and instinct sympathetic and understanding. He is well aware of the crying need in domestic life of the cultivation of those simple basic virtues upon which the maintenance of the home and family depend. He is equally well aware of the crying need of character, integrity and intelligence in public affairs. What body of citizens is better qualified to help in promoting these by precept and example?

Many organizations and individuals outside the medical profession are actively engaged upon these problems at the present moment. Many individuals and organizations within the medical profession and among them members of this Society have for many years waged a valiant battle for the betterment of social and industrial conditions affecting the health and well-being of the community.

The profession as a whole, however, is apathetic, reluctant to venture beyond what seems its legitimate field but as Dr. Shattuck said so many years ago "the horizon opens before us as we go on."

Without relaxing for a moment our efforts along the lines of past endeavor, for the frontiers against disease so hardily won must be maintained and extended, we must at the same time take the offensive against an even more insidious foe infiltrating the fabric of our social welfare.

The active participation by the medical profession in civic, economic and sociological matters affecting the well-being of the people is, I believe, sorely needed to day to avert a social cataclysm threatening the very life of the nation.

We must, like Sir Edward Parry's Arctic party, raise our eyes from the track along which we are plodding to above the horizon if we would measure the progress toward our true objectives.

I would not advocate a return to the teleological views of Galen but a teleology of aim and effort is as essential in medicine as in religion of which it might be considered a part.

The occasion is pressing, the capabilities are at hand, may neither the vision nor the will be found wanting.

A CASE OF POSTENCEPHALITIC PARKINSON'S DISEASE
TREATED BY TOTAL THYROIDECTOMY*

BY ABRAHAM MYERSON, M.D.,† AND DAVID D. BERLIN, M.D.‡

THE rationale which prompted one of us (Abraham Myerson) to select a case of Parkinson's disease for total thyroidectomy is as follows

1 In active untreated cases of Parkinson's disease the metabolism is increased. Thus in a very severe case who was deprived of sedative medication for a week, the metabolism rose to +60 per cent. In several other cases the metabolism has ranged between +15 and +40. When these same cases are given large doses of stramonium or hyoscine with some control of tremulous muscular activity the metabolism drops. These cases will be cited, together with other facts, in a detailed manner, in a later paper.

2 The drugs that are in any way successful in ameliorating the condition of patients with Parkinson's disease lower metabolism.

3 These facts together with the belief that the normal thyroid activation is too great for an organism with defective neuronic links, lead to the hypothesis that if the thyroid were totally removed and the patient allowed to become myxedematous, the myxedema could be controlled and the symptoms would be ameliorated in much the same way that reducing the speed of an engine lessens shaking and rattle in a light or defective machine.

The later facts showed that this rationale of approach is not entirely correct. Nevertheless, the results of operation were quite striking.

CASE HISTORY

Estelle C. aged 32 married had encephalitis at the age of nineteen. In the next two years the patient was quite sleepy, weak, and depressed. This condition persisted moderately until about twelve years ago when she began to notice shaking of the right leg. Gradually this shaking spread to all limbs, face and tongue. The face became stolid, and the patient presented a characteristic Parkinson's syndrome. Her baby was born in 1927. Her symptoms increased. Her condition grew worse despite the varied types of treatment she underwent, and for two months before it was decided to perform a thyroidectomy upon her she had become bedridden. The tremor was as marked as any case we have noted. The churning of the jaws was so great that the saliva became very foamy. She could not feed herself and her speech was almost indistinguishable. At this time she was receiving eight hypodermic injections of 1/50 hyoscine each day together with varying but large doses of luminal and other sedatives.

With grateful acknowledgment to the Greater Boston Bickur Cholim Hospital and the Beth Israel Hospital whose cooperation made this procedure possible and to the patient who fully and freely gave her consent.

†Myerson—Professor of Neurology Tufts College Medical School. Berlin—Assistant Professor of Anatomy Tufts College Medical School. For records and addresses of authors see This Week's Issue page 1234.

She had received during the period of her illness from various neurologists hyoscine, stramonium, harmine, atropin, parathyroid gland, calcium lactate and belladonna. It is noteworthy that 3 gr of stramonium leaves three times a day had no effect. Sterile milk was also employed in the latter part of 1930. Typhoid vaccine was tried for a moderately prolonged period of time. Thus in summarizing the treatment, all forms had been used and even with the most massive doses of hyoscine and other drugs, she had become bedridden and her tremor and rigidity were extreme, the tremor being more noticeable however than the rigidity.

She entered the Greater Boston Bickur Cholim Hospital on June 5, 1929. She was sent to the Beth Israel Hospital on December 5, 1933 where a total ablation of her thyroid was done without incident by Dr. David D. Berlin. Prior to the operation her metabolism was -29. This we ascribed to the enormous doses of hyoscine which she was receiving.

No noticeable improvement occurred during the first two weeks. In fact, when she left the hospital her condition was probably somewhat worse than before the operation. About the third week it was noted that the patient's condition was improving. Gradually as she approached myxedema, manifested by harshness of the skin and a dropping metabolism which reached -35 it became possible to control her condition with much less hyoscine than before. Some time in the early part of February, 1934 the patient was able to get up out of bed, walk, raise her hands and hold them outstretched with but little tremor. There was some definite tremor around the mouth. She could be kept in this condition with three doses of hyoscine a day together with a small dose of luminal. Prior to operation she had complained of pain in her ankles and feet. This pain became the most troublesome of her symptoms.

On March 21, 1934 the note states patient walks with a slight drag of the legs and with a typical Parkinsonian facies and lack of associated movements. Her speech is clear although the voice is weak. There is no noticeable tremor of the face. The tongue protrudes straight is red and without noticeable tremor. There is marked plastic rigidity of the neck. The patient can feed herself. When she raises her arms they are held quite steady. Her grip is fairly firm. There is no swing of tremor to the opposite side when either hand is used although movements of the hands set up an associated tremor which is slight of the mouth. Her arms are not spastic. The patient herself feels very much better. She does not fall asleep so frequently as formerly and she is very grateful for the results.

THE EFFECT OF ELIMINATING THE HYOSCINE

The hyoscine was not administered for two days. During this period the patient became markedly worse and in fact reached her pre-operative stage. She became so tremulous that she could not use her hands. Her speech became very indistinct and the churning of the saliva into foam recurred. When she was put back on hyoscine which is now being administered in two doses of 1/50 gr the symptoms became immediately ameliorated to the point where she is now ambulatory.

The myxedema was easily controlled by a small dose of thyroid, ranging from $\frac{1}{2}$ to $\frac{3}{4}$ gr, per day. We have not tried the effect of large doses of thyroid because it seems likely that this would have the effect of stopping the hyoscine, that is, it would restore the previous helpless condition. The after-care in this case is quite difficult, and it is probable that the patient will require constant medical management.

The patient was demonstrated at the Boston Society of Psychiatry and Neurology on April 26, 1934. She left the Greater Boston Bickur Cholim Hospital for the first time with the exception of her ambulance ride to the Beth Israel Hospital. She was very composed during the automobile trip, got out of the machine by herself, walked up the stairs leading to the place of meeting, was not at all agitated by the presentation before a rather large group, walked around, raised her arms and legs without noticeable tremor, and was driven home in a taxi quite jubilant over her performance.

THE WORKING HYPOTHESIS

We are working on a series of cases and selecting at the present time the hopeless and completely disabled types. The theory that the myxedema in itself would lead to amelioration of symptoms must be modified in view of the fact that when the administration of hyoscine was stopped the patient immediately slumped into her previous condition. The provisional explanation or working hypothesis is that with the thyroid removed, the administration of the hyoscine becomes effective, whereas with a fully operative thyroid the organism is activated against the full effect of the drug.

We do not in the least expect that this is a cure of Parkinson's disease, nor do we know that any other case will react as this one did. The results constitute a valid basis for further work along this line.

THE EFFECT OF DINITROPHENOL ON THE METABOLISM AS SEEN IN SCHIZOPHRENIC PATIENTS*

BY J M LOONEY, M.D.,† AND R G HOSKINS, M.D.‡

IT has been found during the course of our investigation on schizophrenia, that patients suffering from this disorder have lowered basal metabolic rates¹. Previous therapeutic efforts with thyroid preparations appeared to be beneficial in certain selected cases².

The studies on 24 dinitrophenol by Cutting and Tainter^{3, 4, 5} indicated that the basal rates could be increased by the use of this drug without any harmful effect on the patient. It seemed worth while, therefore, to raise the basal metabolic rate in a group of patients by means of this compound and estimate the concomitant changes in various physiological and psychological functions in order to determine whether the beneficial influence of thyroid was due to the increase in the basal metabolic rate, per se, or to other effects of the medicament.

For this purpose ten patients were given 24 dinitrophenol by mouth in gelatine capsules beginning with an initial dose of 30 mg per kilo daily. The medication was continued for a period of seven weeks and increases in the dosage in some cases up to 4 mg per kilo were made whenever it seemed warranted by the individual's reaction.

Analyses were made weekly, beginning two

weeks before the period of medication and continuing for two weeks afterward on both blood and urine. Determinations were made of the oxygen consumption rates three times a week. On the blood, determinations were made for non-protein nitrogen, urea nitrogen, uric acid nitrogen, creatinine nitrogen, sugar, cholesterol, lactic acid, glutathione, carbon dioxide, oxygen and pH. In addition, studies of complete blood cytology were also made. Each week twenty-four hour urine specimens were collected, catheterizations being employed at the beginning and end of the period to insure complete and accurate collection. These were analyzed for total nitrogen, urea nitrogen, ammonia nitrogen, uric acid nitrogen, and creatinine nitrogen. Routine qualitative determinations were made for the presence of sugar, albumin, acetone bodies and bile pigments as well as microscopic examinations for casts, etc.

In the first chart we have given graphs of the weights for each of the ten patients. It will be noted that a gradual loss of weight is experienced in every case, ranging from 0.8 kilo gram to 5.6 kilograms, with an average loss of 2.5 kilograms. Undue loss in weight was combated by keeping the patients on a non-restricted diet and in three cases by supplementary feeding of milk and eggs between meals. For this reason the loss of weight in our patients was much lower than that in the obese patients reported by Cutting⁴ which averaged 0.9 kilo-gram per week.

The oxygen consumption rate was increased

on the average approximately 50 per cent from a mean value of 84 per cent of normal expectation to 123 per cent, as may be seen from the graphs in chart II. One subject was almost completely refractory to the drug in the dos-

This is in contrast with the findings of Cutting, Mehrrens, and Tainter⁴ who found that in non-psychotic subjects the oxygen consumption rate fell to normal within three to four days. Evidences will be noted in two of the charts of

CHART I
BODY WEIGHT

age used. The increase commenced immediately after the taking of the first dose and reached its full effect within a few days. The oxygen consumption rate remained elevated after the administration of the dinitrophenol had been terminated and did not again reach its pre-medication level until ten to fourteen days later.

the erratic and unaccountable elevations in the rate that are often seen in schizophrenic patients. Because of this peculiarity, trends are more significant than individual findings.

There was no appreciable increase in body temperature and the pulse rate, systolic and diastolic blood pressure readings remained approxi-

mately constant This point is worthy of consideration in view of repeated attempts which have been made to produce a formula for predicting the basal metabolic rate from the pulse rate, pulse pressure, and blood pressure determinations

what elevated during the entire period of medication These increases were so marked in the first four patients, in one of whom the non protein nitrogen reached a maximum value of 54.0 mg per 100 ml that the advisability of discontinuing the study was seriously considered How

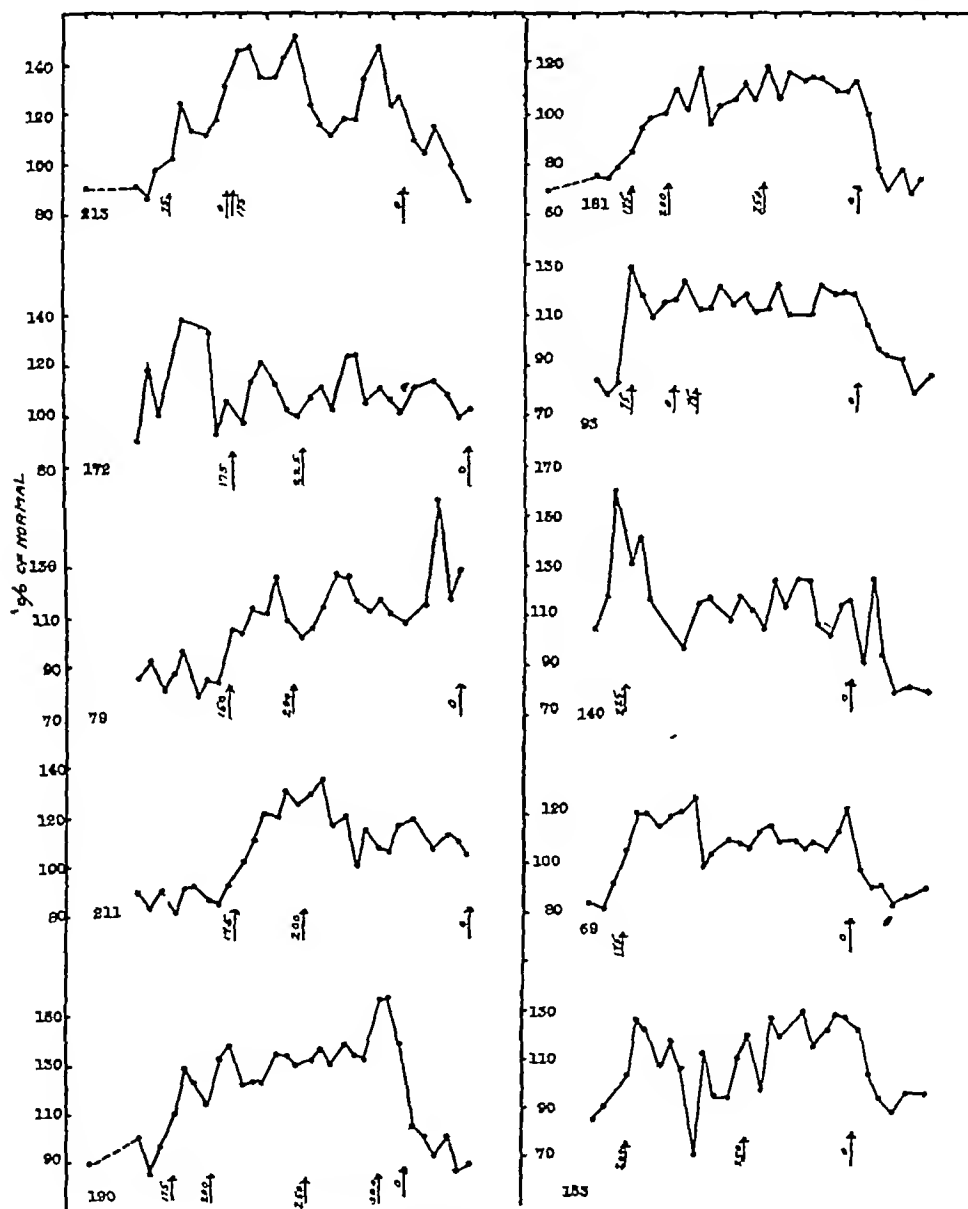

CHART II.
OXYGEN CONSUMPTION RATE.

Observations at irregular intervals. Number of days intervening being indicated by the distance on the horizontal axis (Each space represents five days)

The effect upon the nitrogenous constituents of the blood is somewhat striking, as shown in charts III, IV, V, and VI. In every case there is a diphasic reaction consisting of an initial rise in the nonprotein nitrogen, urea nitrogen, and creatinine nitrogen, and subsequently a fall. The uric acid nitrogen appeared to remain some-

ever, as careful examinations of the urine showed no indication of renal damage and as the following week the nitrogen content of the blood had receded from its high level, it was decided to continue with the medication. In one case only was any gastro-intestinal disturbance noted. This patient vomited a small amount

of watery material during the second week of medication so that on one day no drug was given.

Despite the gradual loss of weight, no evidence of excessive loss of nitrogen was found by quantitative analyses of the urine. There

take The creatinine output fluctuated slightly around the mean value but did not change significantly in either direction. The total urinary volume varied greatly among the individuals, one patient having an average daily output of 1000 ml and another one of 5291 ml, but the

was no characteristic trend in the nitrogen output of these patients, three showing a tendency to excrete more nitrogen, three to excrete less, and the remaining four showing no change. This finding supports that of Magne, Maver, and Plantefol⁴ who reported no increase in nitrogen excretion in dogs on a constant nitrogen in-

volume for each individual remained relatively constant. There was no definite relationship between total urinary volume and total nitrogen output.

The effect of the increased metabolic rate upon the carbon dioxide and oxygen content of the venous blood was also determined. It was

mately constant This point is worthy of consideration in view of repeated attempts which have been made to produce a formula for predicting the basal metabolic rate from the pulse rate, pulse pressure, and blood pressure determinations

volume for each individual remained relatively constant. There was no definite relationship between total urinary volume and total nitrogen output.

The effect of the increased metabolic rate upon the carbon dioxide and oxygen content of the venous blood was also determined. It was

thought that an increased energy exchange in the tissues might be mirrored by an increased output of carbon dioxide and a lowering of the oxygen content of the venous blood. However, no such effect was noted, the carbon dioxide values remaining relatively constant and the oxy-

tween 5 and 20 mg per 100 ml of blood during the period of medication, but no consistent increase. This is indicative of the fact that anoxemia does not occur as a result of the increased demand of the tissues for oxygen. This finding is in agreement with that of Hall et al⁸, who

gen values in some cases showing increases and in others decreases

As previous investigations had shown that the lactic acid content of the blood of schizophrenic patients was significantly higher than that of normal individuals, this was determined by the method of Friedemann and Kendall⁷. The values obtained showed considerable fluctuation be-

found that in dogs even with large doses, 10 to 20 mg per kilo, there was no consistent increase in the lactic acid content of the blood until the terminal stage was reached. The pH of the blood was determined by the glass electrode and electron tube potentiometer of Stadie et al⁹. A slight increase amounting to 0.05 pH was noted in six of the ten cases

No change was noted in either the reduced or total glutathione content of the blood, the values falling between 40 and 50 mg per cent. The blood cholesterol showed marked variation, but no significant trend could be elicited, the values ranged from 122 to 219 mg per 100 ml of blood. The blood sugar values showed a tend-

SUMMARY

In order to study the effect of raising the low basal metabolic rate, which is consistently found in schizophrenic patients, by the use of a dinitrophenol, this drug was administered to ten patients in doses of 3 to 4 mg per kilo for a period of forty-nine days.

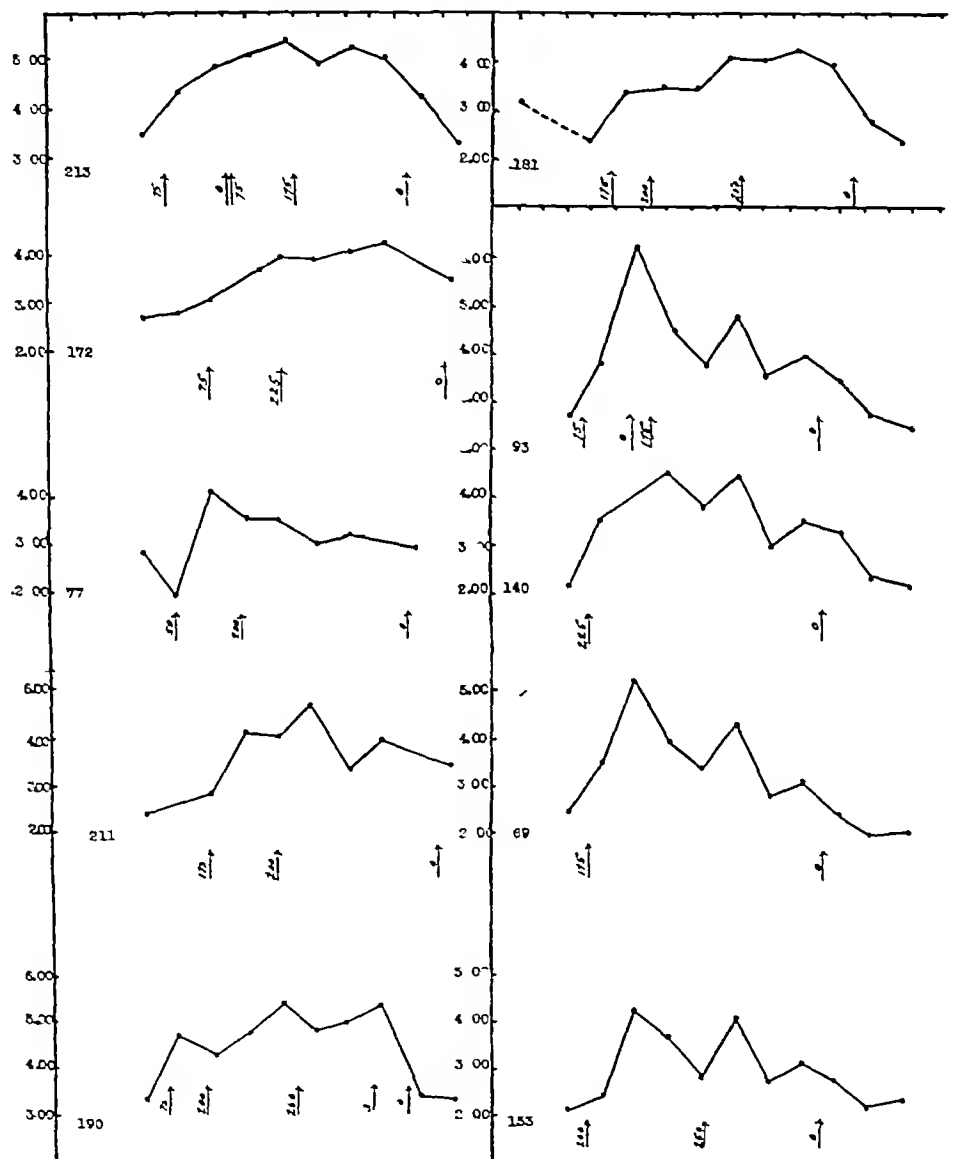

CHART V

Lactic Acid (Blood)

ency to rise, but the increase was not of sufficient magnitude to be regarded as significant.

There was a suggestion that the medication may prove to be of some therapeutic value, but our data are not yet sufficiently extensive to permit accurate judgment.

Each week analyses were made on blood for complete nitrogen partitions, sugar, cholesterol, lactic acid, glutathione, carbon dioxide, oxygen, and pH. Nitrogen partitions were made on urine as well as routine qualitative analyses. It was found that there was an increase in

the basal metabolic rate of approximately 50 per cent without any concurrent change in blood pressure and pulse rate or temperature. At first there was a gradual increase in the non-protein nitrogen, urea nitrogen, and uric acid nitrogen, which again receded to normal as the treatment continued. Blood cholesterol and lactic acid

of weight, especially if the energy intake is augmented by supplemental feeding.

Within the limits of dosage employed, the drug is apparently harmless.

In dosages up to 4 mg per kilo, the drug is without significant effect on temperature, blood pressure, pulse pressure, or pulse rate.

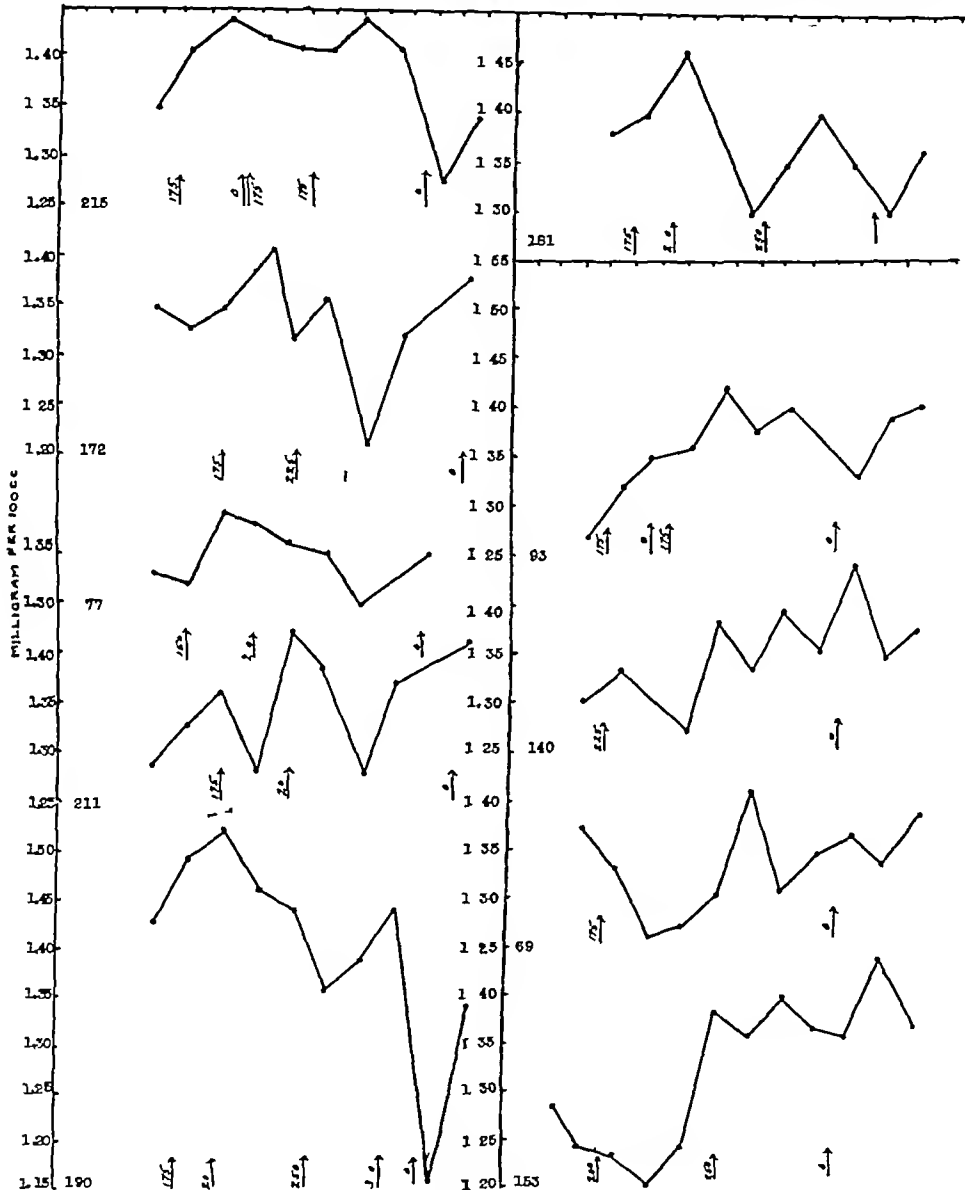

CHART VI
CREATININ (BLOOD)

HYPERTROPHIC ARTHRITIS OF THE HIP*

A Review of Seventy-Nine Patients

BY JOHN O. KUHN'S, M.D.†

THIS study is based on a review of the histories and end-result examinations of seventy-nine patients who were treated for hypertrophic arthritis of the hip in the Robert Breck Brigham Hospital from the opening of its wards in 1914 until 1931. In this group there were 45 females and 34 males. This would suggest that more women suffer from this disability than men, which is contrary to the findings of others¹, but in the entire number of patients treated in the hospital for arthritis of all types during this period there were about twice as many women as men. The ages of the patients with hypertrophic arthritis of the hip at the time of admission to the hospital varied between 36 and 73 years, the average being 56. None of the cases studied were of the type occasionally described in young adults where osseous overgrowth occurs about the margins of one hip joint following severe trauma to the hip, a condition more properly called traumatic arthritis².

The histories of these seventy-nine patients gave interesting, suggestive data in regard to possible causative factors. It was suggested repeatedly that heredity played no part in the development of hypertrophic arthritis³ except in the inheritance of the type of body-build. Hypertrophic arthritis is more apt to attack individuals of the stocky type⁴. There were thirteen patients in this group, members of whose immediate families were afflicted with severe arthritis. But an incidence of this extent (15 per cent) is not high enough to establish any definite familial relationship.

Repeated injury and strain have been mentioned more often than other factors in the past as a cause of hypertrophic arthritis⁵. Trauma is frequently remembered but when described usually appears to have played no major part. In nine of the patients there had been a severe fall or blow upon the hip within several years of the development of the arthritic symptoms. Injury to joints from hard labor also has been considered of etiological importance⁶. In this group there were only fifteen persons engaged in work which could be considered laborious. Obesity has been known to produce

the symptoms of strain in various parts of the body. Twelve of the patients were much overweight, but half of the entire group were below what would be considered their normal weight.

One female patient, aged forty-seven, had an unreduced congenital dislocation of both hips with extensive hypertrophic arthritis in both hips. Posture, as has long been recognized, can alter weight-bearing lines and change the stability of joints such as the hip. In fifty-seven of the patients, all of the cases where mention was made of it the posture was described as poor. In the earlier records no mention was made of the posture. It seemed reasonable to assume that infections in early life which damaged articular tissues might leave such articulations more susceptible to later injury either infectious or mechanical. One man and two women in this number had suffered from rheumatic fever in childhood with involvement of the joints.

The importance of endocrine dysfunction in certain cases of hypertrophic arthritis is scarcely questioned⁷. The thyroid gland or the ovaries are usually considered at fault in such cases. Unfortunately very few basal metabolic tests were taken upon arthritic patients before 1924. In this series a persistently low basal metabolism was found in eighteen patients and a high basal metabolism was observed in three. In four women the arthritic symptoms developed at the climacteric⁸. No other studies on endocrine dysfunction were made except in rare instances.

A possible relationship of disordered intestinal function to hypertrophic arthritis has been mentioned⁹. As there is no unanimity of opinion as to what constitutes disordered intestinal function it is difficult to collect data from records. Unfortunately studies of the stool and tests for the rapidity of intestinal elimination were performed only in the later cases. In this group there were sixteen patients who gave a history of chronic constipation. Eighteen others showed colonic stasis of more than forty-eight hours upon x-ray examination¹⁰.

Among certain students of arthritis the hypertrophic form is still looked upon as an infectious rather than a degenerative process¹¹. Certain findings in the histories of these patients would suggest that infection played some part proba-

This paper is one of a series of studies made in connection with the Robert B. Brigham Hospital Survey of Chronic Disease.
*Kuhn's—Assistant Orthopedic Surgeon Children's and Robert B. Brigham Hospitals. For record and address of author see This Week's Issue page 1234.

bly a secondary one, in the development of their disabilities. It could not be determined clinically and by x-ray whether in these particular cases the original process, hypertrophic arthritis, was wholly an infectious process, or whether the degeneration and trauma had made the articular tissues a more ready prey when infection entered the body. In recent years there has been a tendency to discount the effect of foci of infection in hypertrophic arthritis and the question is still sub judice. Dental infection was found in twenty-eight patients and chronic tonsillar infection was recorded in ten. No definite clinical improvement was observed after the removal of these infections. In seven other patients there was a distinct increase in the arthritic symptoms in the joints showing hypertrophic arthritis during the course of acute infections such as colds, tonsillitis and scarlet fever.

The laboratory data available in this series of patients were for the most part negative. The basal metabolic tests have already been discussed. There was secondary anemia in three patients. The blood counts in all of the others were within normal limits. Determination of the blood serum calcium and phosphorus showed nothing noteworthy. The tolerance for glucose gave the normal readings except where other physiological dysfunction was present as the cause. The blood sedimentation rate was within the normal readings except in the few cases already mentioned where the temperature and clinical course either showed or suggested an infectious process.¹² Hypertension has been commonly found by some observers in hypertrophic arthritis.¹³ In this group there were only ten patients with a systolic blood pressure persistently above 160 mm of mercury.

The x-rays in this series showed the usual findings, rather dense bone, with osseous proliferation about the upper margin of the acetabulum and upon the femoral head. In a few cases there were localized areas of rarefaction in the femoral head and localized areas of ossification about the acetabulum resembling osteophytes.¹⁴ The extent of the anatomical changes did not parallel the severity of the symptoms. No change was observed in the x-ray subsequent to treatment except that in lateral x-rays a decreased forward inclination of the pelvis was observed due to correction of posture and faulty weight-bearing. In a few patients later x-rays showed more extensive changes about the hip joint, usually associated with continuance or increase in severity of symptoms.

The treatment of these patients was wholly conservative, not from lack of competent surgical assistance or from extreme conservatism, but as an attempt to determine what would be the result with as good a regimen of health as could be devised at that time. The earlier cases, from 1914 to 1920, were treated with rest, a

little physiotherapy and local support to the hip, usually a plaster or a leather spica.¹⁵ The results in these early cases were not particularly good. They compare in functional rehabilitation and in relief of pain about equally well with the results of the various surgical procedures which were performed for hypertrophic arthritis, of which reports appeared in the literature during these years.¹⁶ From about 1920 onward came a fuller realization that one was not dealing with a localized disease in the hip alone and the results of treatment improved tremendously with prolonged and adequate rest, physiotherapy devised to correct so far as possible the mechanical inadequacies of the affected hip joints, including general postural exercises and local measures to increase motion and strengthen muscles about the hip itself, and whatever measures were indicated to improve the general health.

It has long been known that constant rest in a position in which there is no strain will usually relieve the muscle spasm and pain in hypertrophic arthritis quite promptly. In the later cases the patients were kept in bed for a prolonged period of time usually two weeks or longer, and the affected hip joint was kept in a position which least resisted the muscle spasm either by pillows and sandbags or with a plaster spica.¹⁷ Walking was not permitted until muscle spasm and pain were almost gone. Heat was used locally to improve the circulation about the hip and to produce muscular relaxation. Massage was used in only a few of the cases since nutrition and strength seemed to improve much more rapidly with supervised active use of the muscles than by the passive stimulation given through massage. The physiotherapy given was not primarily for local comfort but rather to correct the mechanical deficiencies of the body which resulted in strain and acted as aggravating factors in the hypertrophic arthritis. One of the chief factors found in association with poor posture was the markedly increased forward inclination of the pelvis. This, by increasing the lumbar lordosis and changing the pull of the flexor and extensor groups of muscles about the hip joint, decreased its stability and made strain a more constant factor. The thrust of weight and the carriage of the upper part of the body as well as any foot strain were also corrected.

The medical treatment and the general up building measures varied with the individual patient. In all an attempt was made to give a diet adequate in mineral constituents and vitamins, high enough in calories for the individual need, usually low in calories for the obese patients and moderately low in carbohydrates for all. Laxatives were used at first in most of the cases to secure more adequate intestinal elimination. In a few patients where intermittent swelling and pain occurred in various joints

where hypertrophic arthritis of the hip was present, in the presence of a slight persistent increase in temperature and an increased blood sedimentation rate vaccines were used usually after testing for skin reactions. There was appreciable clinical improvement in a small number of these patients after the use of vaccine.¹⁵

Among the early admissions there were many patients who were quite old. A large number of these have since died. Many of these were entirely relieved or much improved in regard to the disabilities in their hip joints for a long period before death.¹⁹ In none of these could any definite relationship be established between the cause of death and the hypertrophic arthritis. The patients died for the most part from the diseases commonly observed in the aged. There were twenty-three deaths in this group of patients. Table 1 gives the causes of death.

It is extremely difficult, in a disease so protean in its manifestations as arthritis, and in individuals who are past middle life, to give accurate end-result data. The advancement of various degenerative processes and intercurrent infections have in a number of instances obscured the functional improvement in the hip joint. The shifting economic status, and the mental unrest in many patients have made it difficult to maintain the improvement which was noted on discharge from the hospital. Most of the patients who are still living have been followed through the out-patient service. A small number have had subsequent admission to the wards due to a recrudescence of symptoms attributable to other diseases. Some of the patients have been helped in finding employment, or in securing better diet and living quarters through the Social Service Department. Table 2 gives a summary of the end-result study.

One hesitates to use the word "well" in these patients. They do not get well in the sense that there is a restoration of normal anatomic structure in the hip joint.²⁰ So far as we know the changes about the hip joint remain. From observations on other joints such as the fingers and knees we do know that the swelling of the soft parts about the joint often subsides permitting freer motion. In about half of those classified

as better a limp remained, but all pain had disappeared and they were able to walk without discomfort. Return of full range of motion at the hip joint following hypertrophic arthritis was observed only in the cases showing slight structural changes in the x-ray. In those listed as better but not working there were three aged

individuals, but the remainder had been unable to find work. We believe that further improvement might have resulted in some of the patients whose disability remained the same if it had been possible to obtain more prolonged hospitalization, more careful supervision at home, or better coöperation on the part of the patient.

Among the six patients listed as worse there were three men, one eighty years old with a recent fracture of the hip, one, an alcoholic of fifty-eight, and one, a man of fifty-six who had refused all medical aid since he had left the hospital. Of the three women, one sixty-three years old, had carcinoma of the breast, one, sixty-five, had severe myocarditis, and a third, a woman of seventy-two, showed progression of the hypertrophic arthritis with increase in the usual infirmities of age. Three patients, all women, could not be traced. Twenty-three, discussed before, had died.

The greater number of these patients had symptoms in other joints as well as in the hip joint. All of them showed multiple articular changes on x-ray examination. There were only twenty-one patients with symptoms limited practically entirely to the hip joint, a condition called *malum coxae senilis* in the older nomenclature of hypertrophic arthritis. The ages of these twenty-one patients ranged between forty-four and seventy-five, all but five were over sixty years of age. All of them had followed active, and for the most part strenuous, occupations. Nine were obese. Table 3 gives the end-result data in this special group. The end-results, as one would expect in this somewhat older group with often far more extensive changes in the hip joint, were less good than in the larger group of seventy-nine. Ten of the sixteen living patients had hip joints functioning so satisfactorily that they could walk without pain.

Conclusions drawn from the data gathered in the study of these seventy-nine patients must necessarily be of a general character since not

one form of therapy, but many, were used in an attempt to keep pace with the changing concepts in hypertrophic arthritis. For this reason comparisons cannot readily be made with earlier studies where but one form of therapy was applied for what was then considered to be a local disease of the hip joint. Then too, none of the early reports followed the patients for long periods of time, so that later changes were

to relieve the greater number of these individuals as this study shows

CONCLUSION

Hypertrophic arthritis of the hip was not found as a disease of the hip alone, other articulations and tissues showed changes on more complete examination. A study of the histories of the patients in this series suggested the interaction of both local and systemic etiologic factors, such as trauma, faulty posture, disordered intestinal function, infections and endocrine disturbances. Data of the end-results showed that progressive deterioration was not necessarily the usual course, even in the aged, when therapy and supervision were continued for a long period of time. Treatment which changed steadily with the increase in our knowledge of this condition was able to relieve the pain and disability in the majority of these patients.

not usually observed and no attempt was made to evaluate the quiescent arthritic disabilities in the presence of the infirmities of old age.

When the etiology of hypertrophic arthritis is definitely established, perhaps our treatment of its disabilities in the hip joint, as well as in other joints, will be more rapid and certain. Our present clinical and pathological studies suggest a multiple etiology²⁰ with structural changes which seem to partake more of a degenerative²¹ than of an infectious process. We must believe that infections play some part in the disease in certain individuals, but in the patients studied this seemed to become evident only after the disease was well established. While lesions similar to hypertrophic arthritis have been produced by interference with the circulation to joints, we cannot establish a definite relationship between local circulatory changes and hypertrophic arthritis²². Articular lesions, either surgical or from external trauma²³, have produced somewhat similar changes. But here again our evidence is not conclusive. Again, what rôle the endocrine glands, or their involution, play in the development of this disease is still conjectural²⁴.

With the development of these suggestions of the causes of hypertrophic arthritis it is not strange that therapy which in the past was almost wholly local and often surgical²⁵, in those advanced cases which came for treatment, has become general and for the most part conservative. Surgery, as Brackett²⁶ stated almost two decades ago, has a very limited application in hypertrophic arthritis and that only in the exceptional case. Further progress should give us new help. With our present knowledge, which we must admit is inadequate, we are able

A CASE OF MULTIPLE CONGENITAL ANOMALIES OF
THE MULLERIAN AND GENITO-URINARY SYSTEMS
WITH ABSENCE OF THE COCCYX*

BY JOHN L. NEWELL, M.D.†

THE reasons for reporting this case are two-fold first, it represents a rare developmental anomaly of the Müllerian system associated with multiple other anomalies, secondly, the symptomatology is exactly explained by the operative findings

The patient, a 26 year-old nulliparous housewife was referred to the Free Hospital for Women in May, 1933 because of fecal incontinence. On admission the complaints were inability to control escape of gas and feces and pain in the lower right side of the abdomen. The fecal incontinence had been present since birth. The pain was first noticed soon after the menarche as an inconstant dull ache. During the next ten years it was never of sufficient intensity to interfere with routine activities but it had been definitely more severe since marriage. For ten months prior to entry the pain had been sharper and on occasions cramplike lasting two to three minutes. These attacks of cramplike pain had a clear relation to the catamenia beginning the day before and lasting throughout the period.

On physical examination the patient was a well developed and well nourished female. The head, neck, chest, extremities and reflexes were normal. The abdomen was soft but there was distinct localized tenderness in the right lower quadrant. No masses were felt. Pelvic examination disclosed a thin rectovaginal septum and complete absence of the perineal body. The anal orifice was relaxed and no sphincter action could be elicited. The vulva and vagina were otherwise normal. The cervix was small as was the fundus which was in left lateral version and in the second degree of retroversion. Nothing could be felt in the right side of the pelvis.

Laboratory data included a negative urine, a normal leucocyte count and a normal blood sedimentation rate. Skiagrams of the gastrointestinal tract were not remarkable. On cystoscopic examination the right ureteral orifice could not be found. Following intravenous pyelography no shadow of the pelvis of the right kidney or ureter was visible. There was no shadow of a right kidney although the left showed clearly.

Although the cause of the abdominal pain was not determined it was felt that the fecal incontinence was the more important complaint. A plastic operation on the anus was performed by Dr. Frank A. Pemberton. No trace of a sphincter could be identified. Convalescence was uneventful. There was some improvement in the fecal incontinence.

Four months later the patient was readmitted because of the pain described above. There was no change in the physical examination. Because of the character and persistence of the abdominal pain an exploratory coeliotomy was performed. The stomach and gall bladder were normal to palpation. The left kidney was about twice normal size but of normal configuration. No right kidney or ureter could be demonstrated. There was a well developed band of peritoneum extending from the umbilicus to the right internal inguinal ring. The obliterated hypogastric artery formed the superior

attachment of this band, the right round ligament forming its inferior free border. The cecum, with a normal appearing appendix lay in a pocket of peritoneum made by this band and the lateral abdominal wall. Mesial to the base of the cecum and

Report of intravenous urography. The right kidney does not show. The left kidney is larger than normal but its calices, pelvis and ureter are normal. There is no evidence of function on the right side. There is some arthritis of the lumbar spine and both sacroiliac joints. The left transverse process of the fifth lumbar vertebra is sacralized. The coccyx is absent.

just above the termination of the right common iliac artery was a globular rudimentary uterus unicornis about 2 cm in diameter, which was firmly attached to the posterior parietal peritoneum by a short fibrous band. The round ligament (described above as forming the free border of an anomalous band of peritoneum) was attached to the lateral side of the uterus. A fully developed tube, 7 cm long having four accessory ostia connected with the top of the uterus. In close proximity and attached to the tube by a ligament of peritoneum was a normal appearing ovary with an active corpus luteum.

A CASE OF MULTIPLE CONGENITAL ANOMALIES OF
THE MULLERIAN AND GENITO-URINARY SYSTEMS
WITH ABSENCE OF THE COCCYX*

BY JOHN L. NEWELL, M.D.†

THE reasons for reporting this case are two fold first, it represents a rare developmental anomaly of the Müllerian system associated with multiple other anomalies, secondly, the symp tomatology is exactly explained by the operative findings

The patient, a 26 year-old nulliparous housewife was referred to the Free Hospital for Women in May 1933 because of fecal incontinence. On admission the complaints were inability to control escape of gas and feces and pain in the lower right side of the abdomen. The fecal incontinence had been present since birth. The pain was first noticed soon after the menarche as an inconstant dull ache. During the next ten years it was never of sufficient intensity to interfere with routine activities but it had been definitely more severe since marriage. For ten months prior to entry the pain had been sharper and on occasions cramplike lasting two to three minutes. These attacks of cramplike pain had a clear relation to the catamenia beginning the day before and lasting throughout the period.

On physical examination the patient was a well developed and well nourished female. The head, neck, chest, extremities and reflexes were normal. The abdomen was soft but there was distinct localized tenderness in the right lower quadrant. No masses were felt. Pelvic examination disclosed a thin rectovaginal septum and complete absence of the perineal body. The anal orifice was relaxed and no sphincter action could be elicited. The vulva and vagina were otherwise normal. The cervix was small as was the fundus which was in left lateral version and in the second degree of retroversion. Nothing could be felt in the right side of the pelvis.

Laboratory data included a negative urine, a normal leucocyte count and a normal blood sedimentation rate. Skiagrams of the gastrointestinal tract were not remarkable. On cystoscopic examination the right ureteral orifice could not be found. Following intravenous pyelography no shadow of the pelvis of the right kidney or ureter was visible. There was no shadow of a right kidney although the left showed clearly.

Although the cause of the abdominal pain was not determined it was felt that the fecal incontinence was the more important complaint. A plastic operation on the anus was performed by Dr. Frank A. Pemberton. No trace of a sphincter could be identified. Convalescence was uneventful. There was some improvement in the fecal incontinence.

Four months later the patient was readmitted because of the pain described above. There was no change in the physical examination. Because of the character and persistence of the abdominal pain an exploratory coeliotomy was performed. The stomach and gall bladder were normal to palpation. The left kidney was about twice normal size but of normal configuration. No right kidney or ureter could be demonstrated. There was a well developed band of peritoneum extending from the umbilicus to the right internal inguinal ring. The obliterated hypogastric artery formed the superior

attachment of this band the right round ligament forming its inferior free border. The cecum, with a normal appearing appendix, lay in a pocket of peritoneum made by this band and the lateral abdominal wall. Mesial to the base of the cecum and

Report of intravenous urography. The right kidney does not show. The left kidney is larger than normal but its calices, pelvis and ureter are normal. There is no evidence of function on the right side. There is some arthritis of the lumbar spine and both sacroiliac joints. The left transverse process of the fifth lumbar vertebra is sacralized. The coccyx is absent.

just above the termination of the right common iliac artery was a globular rudimentary uterus unicornis about 2 cm in diameter, which was firmly attached to the posterior parietal peritoneum by a short fibrous band. The round ligament (described above as forming the free border of an anomalous band of peritoneum) was attached to the lateral side of the uterus. A fully developed tube 7 cm long having four accessory ostia connected with the top of the uterus. In close proximity and attached to the tube by a ligament of peritoneum was a normal appearing ovary with an active corpus intantum.

one form of therapy, but many, were used in an attempt to keep pace with the changing concepts in hypertrophic arthritis. For this reason comparisons cannot readily be made with earlier studies where but one form of therapy was applied for what was then considered to be a local disease of the hip joint. Then too, none of the early reports followed the patients for long periods of time, so that later changes were

to relieve the greater number of these individuals as this study shows

CONCLUSION

Hypertrophic arthritis of the hip was not found as a disease of the hip alone, other articulations and tissues showed changes on more complete examination. A study of the histories of the patients in this series suggested the interaction of both local and systemic etiologic factors, such as trauma, faulty posture, disordered intestinal function, infections and endocrine disturbances. Data of the end-results showed that progressive deterioration was not necessarily the usual course, even in the aged, when therapy and supervision were continued for a long period of time. Treatment which changed steadily with the increase in our knowledge of this condition was able to relieve the pain and disability in the majority of these patients.

not usually observed and no attempt was made to evaluate the quiescent arthritic disabilities in the presence of the infirmities of old age.

When the etiology of hypertrophic arthritis is definitely established, perhaps our treatment of its disabilities in the hip joint, as well as in other joints, will be more rapid and certain. Our present clinical and pathological studies suggest a multiple etiology²⁰ with structural changes which seem to partake more of a degenerative²¹ than of an infectious process. We must believe that infections play some part in the disease in certain individuals, but in the patients studied this seemed to become evident only after the disease was well established. While lesions similar to hypertrophic arthritis have been produced by interference with the circulation to joints, we cannot establish a definite relationship between local circulatory changes and hypertrophic arthritis²². Articular lesions, either surgical or from external trauma²³, have produced somewhat similar changes. But here again our evidence is not conclusive. Again, what rôle the endocrine glands, or their involution, play in the development of this disease is still conjectural²⁴.

With the development of these suggestions of the causes of hypertrophic arthritis it is not strange that therapy which in the past was almost wholly local and often surgical²⁵, in those advanced cases which came for treatment, has become general and for the most part conservative. Surgery, as Brackett²⁷ stated almost two decades ago, has a very limited application in hypertrophic arthritis and that only in the exceptional case. Further progress should give us new help. With our present knowledge, which we must admit is inadequate we are able

A CASE OF MULTIPLE CONGENITAL ANOMALIES OF
THE MULLERIAN AND GENITO-URINARY SYSTEMS
WITH ABSENCE OF THE COCCYX*

BY JOHN L. NEWELL, M.D.†

THE reasons for reporting this case are two-fold first, it represents a rare developmental anomaly of the Mullerian system associated with multiple other anomalies, secondly, the symptomatology is exactly explained by the operative findings

The patient, a 26-year-old nulliparous housewife was referred to the Free Hospital for Women in May, 1933 because of fecal incontinence. On admission the complaints were inability to control escape of gas and feces and pain in the lower right side of the abdomen. The fecal incontinence had been present since birth. The pain was first noticed soon after the menarche as an inconstant dull ache. During the next ten years it was never of sufficient intensity to interfere with routine activities but it had been definitely more severe since marriage. For ten months prior to entry the pain had been sharper and on occasions cramplike lasting two to three minutes. These attacks of cramplike pain had a clear relation to the catamenia beginning the day before and lasting throughout the period.

On physical examination the patient was a well developed and well nourished female. The head, neck, chest, extremities and reflexes were normal. The abdomen was soft but there was distinct localized tenderness in the right lower quadrant. No masses were felt. Pelvic examination disclosed a thin rectovaginal septum and complete absence of the perineal body. The anal orifice was relaxed and no sphincter action could be elicited. The vulva and vagina were otherwise normal. The cervix was small as was the fundus which was in left lateral version and in the second degree of retroversion. Nothing could be felt in the right side of the pelvis.

Laboratory data included a negative urine, a normal leucocyte count and a normal blood sedimentation rate. Skiagrams of the gastrointestinal tract were not remarkable. On cystoscopic examination the right ureteral orifice could not be found. Following intravenous pyelography no shadow of the pelvis of the right kidney or ureter was visible. There was no shadow of a right kidney although the left showed clearly.

Although the cause of the abdominal pain was not determined it was felt that the fecal incontinence was the more important complaint. A plastic operation on the anus was performed by Dr. Frank A. Pemberton. No trace of a sphincter could be identified. Convalescence was uneventful. There was some improvement in the fecal incontinence.

Four months later the patient was readmitted because of the pain described above. There was no change in the physical examination. Because of the character and persistence of the abdominal pain an exploratory coeliotomy was performed. The stomach and gall bladder were normal to palpation. The left kidney was about twice normal size but of normal configuration. No right kidney or ureter could be demonstrated. There was a well developed band of peritoneum extending from the umbilicus to the right internal inguinal ring. The obliterated hypogastric artery formed the superior

attachment of this band, the right round ligament forming its inferior free border. The cecum with a normal appearing appendix, lay in a pocket of peritoneum made by this band and the lateral abdominal wall. Mesial to the base of the cecum and

Report of intravenous urography: The right kidney does not show. The left kidney is larger than normal but its calices, pelvis and ureter are normal. There is no evidence of function on the right side. There is some arthritis of the lumbar spine and both sacroiliac joints. The left transverse process of the fifth lumbar vertebra is sacralized. The coccyx is absent.

just above the termination of the right common iliac artery was a globular rudimentary uterus unicornis about 2 cm in diameter which was firmly attached to the posterior parietal peritoneum by a short fibrous band. The round ligament (described above as forming the free border of an anomalous band of peritoneum) was attached to the lateral side of the uterus. A fully developed tube 7 cm long having four accessory ostia connected with the top of the uterus. In close proximity and attached to the tube by a ligament of peritoneum was a normal appearing ovary with an active corpus luteum.

In the pelvis was a fully developed spindle shaped uterus unicornis, in anterior position, and held in left lateral version by its round ligament, with a normal tube and ovary. The sigmoid and rectum

The patient made an uneventful convalescence. Since her discharge she has been completely free of pain and has thus far had six catamenia, regular in time and amount of flow.

Photomicrographs of sections from the rudimentary uterus. There is some premenstrual proliferation of some of the glands. The dense stroma and the hyperplasia of other glands indicate dysfunction. Magnification 32 X.

filled the right side of the pelvis. No trace of old blood or of endometriosis could be found. A right hemihysterectomy with salpingo-oophorectomy and incidental appendectomy were performed.

On section the uterus had a cavity of 1.5 cm in diameter, which was filled entirely with endometrium, no blood being visible grossly. A pin hole opening communicating with the tube was the only channel to the peritoneal cavity. The tube was normal except for the four accessory ostia. Microscopically a section of the endometrium was moderately hyperplastic and contained only one small area of hemorrhage. The tube and ovary were normal. If the rudimentary uterus menstruated, and the appearance of the endometrium, together with the story of monthly attacks of pain would lead one to assume that it did, the menstrual blood must have passed into the peritoneal cavity via the tube. Careful examination at operation failed to disclose endometriosis or old blood. As there was no hematometra and the ultimate fate of the menstrual blood was not discovered, one would be led to conclude that the uterus did not menstruate and that the pain must have been due to local congestion.

Although a careful search of the literature of the past ten years has been made, only one case in any way comparable with this case was found, viz., that reported by Hart in 1931 in which the rudimentary uterus lay in the broad ligament of the fully developed uterus, no other anomalies being present. In the case herein reported not only was there imperfect development of the right Müllerian duct but also the rudimentary uterus was outside of the true pelvis and had no connection whatsoever with the organs of the left Müllerian duct. Furthermore, the right kidney and ureter, perineal body, anal sphincter and coccyx were absent and there was an anomalous band of peritoneum including the right round ligament and obliterated hypogastric artery.

REPAIR OF ORBICULAR LIGAMENT AT THE ELBOW

BY FREDERIC JAY COTTON, M.D.,* AND GORDON MACKAY MORRISON, M.D.*

NOT very rarely the radial head is torn loose with rupture of the orbicular ligament. This may repair sufficiently well, with the elbow held during repair in flexion, but that is not the rule. Ordinarily, the radial head becomes or remains loose and is pulled upward by the biceps, the tendon of which is inserted on the radial tubercle just below the radial neck. Such cases call for repair.

*Cotton and Morrison—For records and addresses of authors see page 817 issue of April 12, 1934.

Access to the region is easy if one sticks to the interval between supinator longus and biceps above, identifies the radial nerve and retracts it outward with the supinator. The biceps tendon is the guide to the radial neck under which lie the torn remnants of the orbicular ligament. With good luck, even after a number of weeks, one may unroll ends of the broken ligament sufficiently to suture with chromic gut. If so, good. If there is not enough left of the ligament to joint the torn ends, various operations have

been tried, apparently without consistent results

Therefore, a case some years ago forced the contriving of a better way. It proved not only efficient, but so simple as to deserve recording.

The wound of entry was as noted above. The lesion was old, and there was no discoverable remnant of ligament.

ORBICULAR LIGAMENT

Upper figure—View from outer side of elbow

1 2 The neck of the radius about which the orbicular ligament should fit

3 The lesser sigmoid cavity against which the radial head should rotate

4 5 The site of the drill holes on the radial (outer) side of the ulna

Lower figure—Elbow from inner side

6 The artificial (fascial) ligament

7 The knot tied in the ends of the fascia where they emerge from the bone. Knot secured with silk sutures

The dotted lines indicate the course of the two ends of the fascial strip through the bone to the common hole of exit where the ends of the strip are knotted.

The radial head was readily reducible. An accessory incision was then made just to the inner side of the presenting point of the ulna. The flexor muscle was stripped away from the inner side of the ulna for a space. Then from

the anterior incision a heavy drill was set on one side of the radial neck, entering as near as might be, one edge of the lesser sigmoid cavity, driven through the ulna to the inner surface against a retractor blade between the ulna and the muscle. The drill, withdrawn, was reinserted on the other side of the radial neck, and so directed as to emerge through the same point of exit from the bone as before.

The ends of a stout strip of fascia from the thigh passed across the radial neck were then passed down on either side of the radial neck, both emerging through the same hole (widened a bit with the curette). The fascia ends, pulled on, dragged the radial head into place. They were then tied in a knot which jammed tight in the hole of exit in the tying. The square knot was then completed, the knot caught with a chromic gut stitch in the usual way, the flexor muscle pulled back to cover it, and the wounds closed.

The boy was then 11 years old. Reexamination March 27, 1934. He is 15 years old and has a perfectly useful arm, normally developed. There is, however, some limitation of supination. Other motions were free. X-ray shows head of radius slightly distorted, apparently influenced by the pull of the encircling ligament, and the head lies a little forward, not in normal contact with its bed on the ulna. Ossification is evident and about the ligament traversing the ulna. All epiphyses are already solidly merged with the shafts.

This operation proved very simple, and very satisfactory.

We have had no chance to repeat it, oddly enough.

It is here presented as probably the simplest efficient technique, to date.

MEDICAL PROGRESS

PROGRESS IN PROCTOLOGY

BY E. PARKER HAYDEN, M.D.*

FROM a rather large number of papers on subjects pertaining to the colon and rectum, the following have been selected for review, as representing points of interest or advance in the study of this field of medicine.

HEMORRHOIDS

There are two facts with regard to the treatment of internal hemorrhoids which are not generally appreciated.

The first is this: that the clamp and cautery operation has been abandoned by almost all, if not all, of the men specializing in rectal surgery.

Hayden—Surgeon to Out Patients and Chief of Rectal Clinic, Massachusetts General Hospital. For record and address of author see "This Week's Issue" page 1234.

in this country. Excision and ligation procedures have supplanted the cautery method because of certain definite advantages which they possess, i.e., more accurate removal of the piles, better hemostasis, freedom from the added trauma of burning, a more comfortable convalescence.

The second fact is that the treatment of internal hemorrhoids by the injection of sclerosing solutions, although definitely not so permanently curative as an operation well done, is nevertheless a very prompt and efficient method of relieving the symptoms which internal hemorrhoids produce, bleeding and protrusions. The degree of permanency of the result varies with

the size of the piles treated and the number and strength of the treatments given

Fansler¹ describes a new plastic operation intended to be used in cases of prolapsed, thrombosed internal piles with perianal edema and thrombosis all around the anal outlet. It is based on the old Whitehead operation but is designed to avoid the chief objections to the Whitehead, that is, stricture and subsequent mucous membrane protrusion. Fansler incises each hemorrhoid at the junction of squamous and columnar epithelium, dissects a flap back to the outside skin, and excises all the underlying varices and thromboses, including removal of the internal pile up to normal mucous membrane above. The flaps thus created and which are attached externally, are sutured to mucous membrane, thus relining the anal canal. Healing has taken place without incident except in one case in which one flap failed to unite and had to be excised.

In view of increasing interest, on the part of medical men throughout the country, in the injection treatment of hemorrhoids and of prolapse of the rectal mucosa, a study by Rosser and Wallace² is timely. This investigation is a sequel to that reported by Rosser in 1931 on "Chemical Rectal Stricture" from the use of oil injection solutions.

In twenty cases with rectal occlusion from submucosal tumefactions, biopsy was secured in eight, and disclosed the swellings to be foreign body granulomas from unabsorbed oil.

Twenty-four experimental injections were then carried out in human beings and biopsy was done in all cases at varying intervals. Three oils were used, olive, mineral, and cottonseed. In six cases injected with olive oil, the rate of absorption was quite rapid, and tumor formation did not occur. The biopsies were performed in from one minute to two months after injection. Mineral oil was used in five cases, all of which developed tumefactions. Cottonseed oil was injected in thirteen cases with biopsy in from three days to ten months. Tumors did occur, but not always, and seemed to depend on the amount of oil used. Addition of phenol to the oil in certain instances seemed to make no difference in the result except that slough occurred in strengths of over ten per cent.

Rosser refers to some experiments done nine years ago by Weidman with the same oils. Multiple subcutaneous injections in two monkeys gave about the same results, viz., no tumors with olive oil, seventy-five per cent of tumors with mineral oil, twelve and a half per cent with cottonseed oil.

In patients with this sort of tumefaction obstinate constipation is the chief symptom, due to rigidity of the rectal wall.

The lesson from these experiments would seem to be clear, to stick to olive oil solutions or to non-oily injection solutions such as quinine and urea hydrochloride.

PROLAPSE

Martin³ proposes a classification of prolapse of the rectum as follows: first degree—an invagination of the sigmoid into the upper rectum, second degree—the prolapse is visible externally but the anus has not everted, third degree—complete anorectal prolapse. These are, as the classification suggests, progressive steps in the descent of a lax lower bowel. Quite a different matter is the simple mucous membrane prolapse, often seen in children.

An operation, first suggested by Lenormant in 1907, is urged by Martin as being a permanent cure. It consists briefly in anchoring the lateral longitudinal band of the sigmoid, previously pulled taut, to the tendon or body of the psoas minor muscle exposed for several inches through a vertical incision in the overlying peritoneum. Iliac fascia is utilized if the psoas minor is congenitally absent.

Read⁴ has utilized a simple but ingenious method of curing irreducible prolapse of the rectum, using the method in four cases: two at Peiping Union Medical College in 1925 and two since that time in Cincinnati. One end of a rubber tube of fair size is slipped into the rectum through the prolapse and anchored to the bowel at the apex of the protrusion. This serves to carry gas and feces out of the rectum and can be utilized for enemata. An elastic band is then applied so as to encircle the prolapse at the anal margin and with enough firmness and elasticity to shut off the blood supply. Care is taken to be sure that the prolapse contains no herniated small bowel, in a peritoneal sac, or bladder. After two weeks the prolapse has sloughed off and good union has taken place at the anal margin without any impairment of sphincter control.

FISTULA

Chisholm⁵ sketches the views of various German authors on the etiology of anal fistula. Five are quoted as believing tuberculosis to be the basis of half or more of the cases, while one author found it in only 6.9 per cent or seventy-two cases by macroscopic and microscopic examination. Petter and Fansler, from a study of 101 cases of abscess and fistula in a tuberculosis sanatorium, concluded that tuberculous fistulae are nearly always secondary to a lesion elsewhere. These 101 cases comprised 5.8 per cent of the total patients examined. A reliable proof of tuberculosis consists in (1) exudate in guinea pig, (2) macerated tissue in guinea pig, (3) tissue section.

Several other contributions are reviewed, all of which give greater or less prominence to the factor of tuberculosis in association with fistula.

Chisholm studied 155 cases of abscess or fistula, 106 of which were negative for pulmonary tuberculosis clinically and by x-ray. Of the re-

maunder, eighteen had pulmonary tuberculosis in the arrested stage and in thirty-one it was active. None were last stage cases. In the investigation specially raised non-tuberculous guinea pigs were used. His results were as follows:

1. In the thirty-one active cases the tubercle bacillus was isolated from the fistula by culture and guinea pig in twenty-four cases. Only one of these had a typical pathologic picture.

2. Of the eighteen arrested cases the bacilli were present in ten by culture and guinea pig, and three showed, histologically, giant cells and tubercles.

3. In the 106 cases clinically and roentgenologically negative none showed tuberculosis by culture or guinea pig.

4. Acid fast bacilli are rarely found in smears of the fistula exudate.

Hayden^a analyzed 388 cases of anal fistula admitted to the Massachusetts General Hospital in the years 1921 to 1930, and secured end results in 280 cases. A rate of cure of 92 per cent in complete incision and drainage operations contrasted with only 50 per cent of cures in the cases operated in other ways. There were three times as many males as females in the series. Two thirds of the patients had delayed from six months to eighteen years before coming to the hospital. Multiple internal openings of a single fistula occurred in three cases and there were four cases of double fistula. Tuberculosis of the fistulous tract was established in only two out of eighty-one cases in which a pathological examination of the fistulous tracts had been done. There were thirty-four patients, however, who had had tuberculosis in one form or another. Also of the thirty-seven patients who had died since their hospital admission, fifteen died of tuberculosis.

The difficulty of establishing the presence of tuberculosis in a fistulous tract merely by tissue section microscopic examination is well known, and it is undoubtedly true that all three methods of diagnosis as listed by Chisholm, should be used. I am convinced, however, that the incidence of tuberculous fistula, except in individuals with active tuberculosis elsewhere in the body, is extremely low.

STRICTURE

The "ano-rectal syndrome" of lymphogranuloma inguinale (the fourth venereal disease).

Lymphogranuloma inguinale (climatic bubo) has long been a familiar disease in the tropics, and a recognized clinical entity with subacute and chronic inguinal adenitis suppuration and sinus formation. The disease is acquired through intercourse presumably due to a specific filtrable virus with an insignificant and often unnoticed, primary lesion on the genitalia.

Glandular swelling occurs in from ten days to three weeks after exposure. Considerable attention has been directed recently toward the *ano-rectal manifestations* of this disease, though these were described in 1848 by Huguier.

DeWolf and Van Cleve^b have summarized our present knowledge of the disease and have reported on their experimental work at Cleveland City Hospital. In 1925 Wilhelm Frei published his specific test for the disease: an intradermal inoculation of sterilized pus from the inguinal glands, giving a characteristic erythema and papule in persons who have, or have had, the disease. DeWolf and Van Cleve applied this test to 1010 people with fifty-eight positive results, using antigens prepared from eleven of these patients. Of the fifty-eight, thirty-one had active adenitis when studied, four had been treated for the disease two to four and one half years before the period of the study; twenty gave a history of persistent inguinal adenitis some time in the past twenty-five years and three had anorectal disease without any evidence or history of inguinal adenitis. One of these three cases did have cerebrospinal syphilis, the other two were negative. The Frei test was strongly positive in all.

The authors recommend investigation of all rectal strictures from this standpoint.

Cole^c has published more recently an article dealing especially with the relation of this disease to rectal stricture. Females are more prone to rectal involvement than males and less likely to have inguinal enlargement due to the free lymphatic drainage distribution of the vagina to the perirectal nodes. There may develop an extensive multiple fistulous involvement of vulva, perineum, and rectum with elephantiasis of the tissues and often a stricture of the lower rectum. This condition was formerly known as the "ano-rectal syphiloma of Fournier" following Fournier's description of it in 1875, but is not due to syphilis as Fournier thought. The advent of the Frei test made it possible to definitely establish the nature of these cases and has proved them to be an ano-rectal manifestation of lymphogranuloma inguinale. Cole reports fifteen cases with ano-rectal involvement in the past year, thirteen females and two males, twelve Negroes and three whites. All had positive Frei tests. Two of the female Negroes had extensive fistulous involvement of the vulva and perianal region, the *esthiomene* of French writers. An acute proctitis with resultant stricture formation occurs and cauliflower-like indurated lesions of the immediate perianal region often develop. Cole has collected in addition thirty-seven cases of inguinal adenitis with positive Frei tests in the past year.

Microscopically this tissue and the sections of the glands exhibit the characteristics of a gran-

the size of the piles treated and the number and strength of the treatments given

Fansler¹ describes a new plastic operation intended to be used in cases of prolapsed, thrombosed internal piles with perianal edema and thrombosis all around the anal outlet. It is based on the old Whitehead operation but is designed to avoid the chief objections to the Whitehead, that is, stricture and subsequent mucous membrane protrusion. Fansler incises each hemorrhoid at the junction of squamous and columnar epithelium, dissects a flap back to the outside skin, and excises all the underlying varices and thromboses, including removal of the internal pile up to normal mucous membrane above. The flaps thus created and which are attached externally, are sutured to mucous membrane, thus relining the anal canal. Healing has taken place without incident except in one case in which one flap failed to unite and had to be excised.

In view of increasing interest, on the part of medical men throughout the country, in the injection treatment of hemorrhoids and of prolapse of the rectal mucosa, a study by Rosser and Wallace² is timely. This investigation is a sequel to that reported by Rosser in 1931 on "Chemical Rectal Stricture" from the use of oil injection solutions.

In twenty cases with rectal occlusion from submucosal tumefactions, biopsy was secured in eight and disclosed the swellings to be foreign body granulomas from unabsorbed oil.

Twenty-four experimental injections were then carried out in human beings and biopsy was done in all cases at varying intervals. Three oils were used, olive, mineral, and cottonseed. In six cases injected with olive oil, the rate of absorption was quite rapid, and tumor formation did not occur. The biopsies were performed in from one minute to two months after injection. Mineral oil was used in five cases all of which developed tumefactions. Cottonseed oil was injected in thirteen cases with biopsy in from three days to ten months. Tumors did occur but not always, and seemed to depend on the amount of oil used. Addition of phenol to the oil in certain instances seemed to make no difference in the result except that slough occurred in strengths of over ten per cent.

Rosser refers to some experiments done nine years ago by Weidman with the same oils. Multiple subcutaneous injections in two monkeys gave about the same results, viz., no tumors with olive oil, seventy-five per cent of tumors with mineral oil, twelve and a half per cent with cottonseed oil.

In patients with this sort of tumefaction obstinate constipation is the chief symptom, due to rigidity of the rectal wall.

The lesson from these experiments would seem to be clear to stick to olive oil solutions or to non-oil injection solutions such as guanine and urea hydrochloride.

PROLAPSE

Martin³ proposes a classification of prolapse of the rectum as follows: first degree—an invagination of the sigmoid into the upper rectum, second degree—the prolapse is visible externally but the anus has not everted, third degree—complete anorectal prolapse. These are, as the classification suggests, progressive steps in the descent of a lax lower bowel. Quite a different matter is the simple mucous membrane prolapse, often seen in children.

An operation, first suggested by Lenormant in 1907, is urged by Martin as being a permanent cure. It consists briefly in anchoring the lateral longitudinal band of the sigmoid, previously pulled taut, to the tendon or body of the psoas minor muscle exposed for several inches through a vertical incision in the overlying peritoneum. Iliacus fascia is utilized if the psoas minor is congenitally absent.

Reid⁴ has utilized a simple but ingenious method of curing irreducible prolapse of the rectum, using the method in four cases, two at Peiping Union Medical College in 1925 and two since that time in Cincinnati. One end of a rubber tube of fair size is slipped into the rectum through the prolapse and anchored to the bowel at the apex of the protrusion. This serves to carry gas and feces out of the rectum and can be utilized for enemata. An elastic band is then applied so as to encircle the prolapse at the anal margin and with enough firmness and elasticity to shut off the blood supply. Care is taken to be sure that the prolapse contains no herniated small bowel, in a peritoneal sac or bladder. After two weeks the prolapse has sloughed off and good union has taken place at the anal margin without any impairment of sphincter control.

FISTULA

Chisholm⁵ sketches the views of various German authors on the etiology of anal fistula. Five are quoted as believing tuberculosis to be the basis of half or more of the cases, while one author found it in only 6.9 per cent or seventy-two cases by macroscopic and microscopic examination. Petter and Fansler, from a study of 101 cases of abscess and fistula in a tuberculosis sanatorium, concluded that tuberculous fistulae are nearly always secondary to a lesion elsewhere. These 101 cases comprised 5.8 per cent of the total patients examined. A reliable proof of tuberculosis consists in (1) exudate in guinea pig, (2) macerated tissue in guinea pig, (3) tissue section.

Several other contributions are reviewed, all of which give greater or less prominence to the factor of tuberculosis in association with fistula.

Chisholm studied 155 cases of abscess or fistula, 106 of which were negative for pulmonary tuberculosis clinically and by x-ray. Of

fifty cases was there found a definite single nerve trunk and then only for a distance of 1 to 2 cm. Eight cases had several parallel fibers, twenty-nine had typical plexuses, and one had an arch shaped plexus. In about one-third of the fifty cases the fibres lay entirely over the left half of the interiliac trigone. These nerve trunks do not adhere to the peritoneum, in contrast to the ureters which are adherent, a practical point of value in dissecting this region. The plexus in every case terminates in the two hypogastric nerves which are always separate at the promontory.

Elaut advises, as an approach for neurotomy, a vertical incision directly over the bifurcation of the aorta, searching laterally for the nerves.

UNUSUAL TUMORS

Rankin and Larson¹⁴ report four cases of mesosarcoma of the rectum, a rather rare tumor. All four patients were men in the fifth and sixth decades. The chief symptoms were constipation, straining at stool, and urinary difficulties. These tumors lie close to the internal sphincter, involve the mucous membrane only late in the disease, are slow growing, metastasize late, but show a marked tendency to local recurrence.

Marino¹⁵ describes a case of primary melanoma of the rectum. It occurred at the anal outlet, was 2x3 cm. in size, and resembled a thrombosed gangrenous hemorrhoid. Although a wide local excision was performed, groin metastases had already taken place, were observed six months later, and the patient died about a year after the operation. There was no local recurrence.

CARCINOMA

Lahev¹⁶ has applied with success the so-called Mikulicz method of closure to resections of the cecum and ascending colon. This method with modifications has been in use quite generally in resections of the left colon for many years and has undoubtedly been a large factor in the reduction of mortality from peritonitis following left colon resections. In the right colon where anastomosis following resection has to be performed between the ileum and transverse colon, this method has never been emphasized if indeed it has been described at all. Lahev resects with clamps and cautery, then brings the ileum and transverse colon out of the incision together, leaving clamps on the ends. If desirable to immediately open the ileum because of preoperative obstruction, he "staggers" the ileum, allowing it to protrude several inches beyond the colon end and then ties a Mixer tube in the ileum. The cut end of the ileum with its tube can thus be laid over on the abdomen beyond the incision, reducing chance of

contamination of the incision. Later the excess ileum is cut away to the level of the colon end, and the intervening spur clamped in seven to ten days. Closure of the two bowel ends is accomplished extraperitoneally in four to six weeks, with drainage of the subfascial space.

There would seem to be little doubt that this procedure is safer than any of the others used in resections of the cecum and ascending colon, although the mortality with preliminary ileocolostomy and secondary resections is also low. The method described by Lahev has the added advantage of removal of the growth at the first operation.

Raiford¹⁷ has analyzed twenty-two cases of carcinoma of the transverse colon which comprised 73 per cent of 297 cases of carcinoma of the entire colon and rectum. At operation 27 per cent of the twenty-two cases showed liver involvement and in 32 per cent the stomach was involved in the growth, either by omental lymphatic channels or by contiguity. Glands were involved in only five cases.

Eighteen cases were radically operated with six postoperative deaths—33 1/3 per cent mortality. Of these two developed peritonitis, two pneumonia, one embolism, and one shock. There were three five-year cures, three cures under five years, two died of recurrence, and four were untraced.

Operative procedures were sketched and the twenty-two case reports presented. Of interest was the presence of achlorhydria in the majority of cases.

Rankin and Olson¹⁸ reviewed 453 cases of carcinoma of the colon operated upon at the Mayo Clinic in the years 1907 to 1927, and attempted to evaluate factors contributing to the prognosis. Lesions of the rectum and rectosigmoid were not included. The size of the lesion at time of operation averaged about the same in the five-year cures as in the dead cases. The five-year cure rate in the right colon was 57.6 per cent as compared with 47.7 per cent in the left colon. Those cases in which the dominant direction of growth was toward the lumen of the bowel yielded 62 per cent of five-year cures as against 41 per cent in the cases where the direction of growth was mainly toward the serosa. As would be expected, the cases without involvement of neighboring glands showed a much higher five-year cure rate than those with metastases.

The degree of malignancy according to Broders' grading was the greatest factor in the prognosis. Both the five-year cure rate and the average postoperative life were greatest in the Grade I cases, becoming progressively less down to the Grade IV's. Nodal involvement became increasingly frequent from Grade I to Grade IV.

Emphasis was laid on the value of decompression.

uloma and are easily confused with the picture of tuberculosis and syphilis.

Treatment is not very satisfactory, though cases with adenitis have been cured by extirpation of the affected glands. On the other hand this may produce elephantiasis of the leg. Suppurating nodes should be drained. Various drugs have been tried without any convincing results. Cole advises rest in bed, free drainage, perhaps partial extirpation of nodes, and antimony and potassium tartrate intravenously. When the process is advanced, with rectal stricture, etc., no therapy can be expected to accomplish a great deal.

Martin⁹ reports a study of twenty-five cases of rectal stricture in female Negroes. Application of the Frei test resulted in a positive diagnosis of lymphogranuloma inguinale in twenty cases, a very impressive result.

David and Lauer¹⁰ have analyzed 104 cases of rectal stricture, seen at Cook County Hospital and in private practice. Nineteen were congenital and the remainder acquired. Of the acquired strictures, twenty-two were due to postoperative scarring following a variety of procedures, while thirty-three were the result of inflammatory processes of different types. Four of these were gonorrheal and three were due to *hyperplastic tuberculosis*. The latter fact is of considerable interest, since this disease occurs so much more commonly in the cecum. Eleven cases were due to tumors of the rectum and sixteen to extrarectal tumors, primary or metastatic. The remaining three cases in the series were the result of perirectal inflammatory processes, one of which was associated with Hodgkin's disease.

Among the thirty-three inflammatory strictures the authors grouped twelve as "venereal strictures ? syphilis." About 50 per cent of these had positive Wassermann reactions but none responded to antisyphilitic treatment. Sulzberger, in a subsequent communication in the J A M A suggests that these twelve cases are probably examples of lymphogranuloma inguinale, and might be so established by application of the Frei test.

HYPERPLASTIC TUBERCULOSIS OF THE COLON

Rankin and Major¹¹ report, from the Mayo Clinic, sixty-five cases of hyperplastic tuberculosis of the large bowel, emphasizing that this form of tuberculosis is largely a surgical problem whereas tuberculous colitis is entirely a medical one. They quote statistics of Park and Krumweide to the effect that in 59 per cent of cases under the age of five the bovine bacillus is the infecting agent. This is true in 46 per cent of cases from ages five to sixteen, and in 22 per cent of adults. The series of sixty-five cases here reported embraced thirty-seven males and twenty-eight females. There were twenty-three cases between ages twenty-one and thirty, and the incidence diminished to only two cases be-

tween sixty and seventy. One case occurred in each of the first two decades. Pain and loss of weight were prominent in 91 per cent of the cases, obstructive symptoms and diarrhea being also quite common symptoms.

Ileocolostomy was done in thirteen cases without mortality, but six died of pulmonary tuberculosis in the first year. Six others were only partially improved, leaving one case as a three year cure.

Resection with ileocolostomy was performed in fifty cases. Four died in the first month, five in the first year (four of these had extensive generalized tuberculosis), four in the second year (one of these had extensive pulmonary disease), and one died six years later of recurrent disease in the intestine. Twelve cases were followed and found to be alive, but their condition was not definitely ascertained. Of the remaining twenty-four cases, one showed no improvement, two moderate gain, and seventeen were entirely well from three months to ten years.

These statistics lead the authors to the definite conclusion that resection with anastomosis is the operation of choice in hyperplastic tuberculosis of the large bowel.

ACTINOMYCOSIS

Bensaude¹² has collected from the literature twenty cases of actinomycosis primary in the anus and rectum. The lesion is essentially a perirectal thickening with abscess formation and without involvement of the mucous membrane except in the late stage of the disease when fistulae develop. Diagnosis is made from the characteristic yellow granules in the pus, as in actinomycosis elsewhere. Inguinal adenopathy is uncommon. Only one case of the twenty was cured, death in the others being caused by local spread of infection and amyloid degeneration of parenchymatous organs, with or without septicemia. Wide surgical excision is advised, if possible, otherwise simple drainage is used, augmented by the use of iodides.

RELIEF OF INTRACTABLE PAIN

A study by L. Elaut¹³ of Ghent, Belgium, based on fifty anatomic dissections, should be of great interest to anyone concerned with the relief of pain in advanced and inoperable rectal cancer. Elaut demonstrated the fact that often there does not exist a definite presacral nerve but rather a plexus which follows one of several general conformations. He prefers to use the term "superior hypogastric plexus", as the plexus lies not in front of the sacrum but higher up in the lower prelumbar region, in the so-called "interiliac trigone", an inverted triangle whose base is a line across the sacral promontory and whose apex is the aortic bifurcation above. The plexus is spread out over 2 to 3 cm, above the sacral promontory. In only twelve of the

fifty cases was there found a definite single nerve trunk and then only for a distance of 1 to 2 cm. Eight cases had several parallel fibers; twenty-nine had typical plexuses, and one had an arch-shaped plexus. In about one-third of the fifty cases the fibres lay entirely over the left half of the interiliac trigone. These nerve trunks do not adhere to the peritoneum, in contrast to the ureters which are adherent, a practical point of value in dissecting this region. The plexus in every case terminates in the two hypogastric nerves which are always separate at the promontory.

Elant advises, as an approach for neurotomy, a vertical incision directly over the bifurcation of the aorta, searching laterally for the nerve.

UNUSUAL TUMORS

Rankin and Larson¹⁴ report four cases of rhabdomyosarcoma of the rectum, a rather rare tumor. All four patients were men in the fifth and sixth decades. The chief symptoms were constipation, straining at stool and urinary difficulties. These tumors lie close to the internal sphincter, involve the mucous membrane only late in the disease, are slow growing, metastasize late, but show a marked tendency to local recurrence.

Marmo¹⁵ describes a case of primary melanoma of the rectum. It occurred at the anal outlet, was 2 x 3 cm. in size, and resembled a thrombosed gangrenous hemorrhoid. Although a wide local excision was performed, groin metastases had already taken place, were observed six months later, and the patient died about a year after the operation. There was no local recurrence.

CARCINOMA

Lahey¹⁶ has applied with success the so-called Mikulicz method of closure to resections of the cecum and ascending colon. This method with modifications has been in use quite generally in resections of the left colon for many years and has undoubtedly been a large factor in the reduction of mortality from peritonitis following left colon resections. In the right colon where anastomosis following resection has to be performed between the ileum and transverse colon, this method has never been emphasized if indeed it has been described at all. Lahey resects with clamps and cautery then brings the ileum and transverse colon out of the incision together, leaving clamps on the ends. If desirable to immediately open the ileum because of preoperative obstruction he "staggers" the ileum, allowing it to protrude several inches beyond the colon end and then ties a Mixer tube in the ileum. The cut end of the ileum with its tube can thus be laid over on the abdomen beyond the incision, reducing chance of

contamination of the incision. Later the excess ileum is cut away to the level of the colon end, and the intervening spur clamped in seven to ten days. Closure of the two bowel ends is accomplished extraperitoneally in four to six weeks, with drainage of the subfascial space.

There would seem to be little doubt that this procedure is safer than any of the others used in resections of the cecum and ascending colon, although the mortality with preliminary ileocolostomy and secondary resections is also low. The method described by Lahey has the added advantage of removal of the growth at the first operation.

Raiford¹⁷ has analyzed twenty-two cases of carcinoma of the transverse colon which comprised 7.3 per cent of 297 cases of carcinoma of the entire colon and rectum. At operation 27 per cent of the twenty-two cases showed liver involvement and in 32 per cent the stomach was involved in the growth either by omental lymphatic channels or by contiguity. Glands were involved in only five cases.

Eighteen cases were radically operated with six postoperative deaths—33 1/3 per cent mortality. Of these two developed peritonitis, two pneumonia, one embolism, and one shock. There were three five-year cures, three cures under five years, two died of recurrence, and four were untraced.

Operative procedures were sketched and the twenty-two case reports presented. Of interest was the presence of achlorhydria in the majority of cases.

Rankin and Olson¹⁸ reviewed 453 cases of carcinoma of the colon operated upon at the Mayo Clinic in the years 1907 to 1927 and attempted to evaluate factors contributing to the prognosis. Lesions of the rectum and rectosigmoid were not included. The size of the lesion at time of operation averaged about the same in the five-year cures as in the dead cases. The five-year cure rate in the right colon was 57.6 per cent as compared with 47.7 per cent in the left colon. Those cases in which the dominant direction of growth was toward the lumen of the bowel yielded 62 per cent of five-year cures as against 41 per cent in the cases where the direction of growth was mainly toward the serosa. As would be expected, the cases without involvement of neighboring glands showed a much higher five-year cure rate than those with metastases.

The degree of malignancy according to Broders' grading was the greatest factor in the prognosis. Both the five-year cure rate and the average postoperative life were greatest in the Grade I cases becoming progressively less down to the Grade IV's. Nodal involvement became increasingly frequent from Grade I to Grade IV.

Emphasis was laid on the value of decompression.

sion of the colon and rehabilitation of the patient in lowering operative mortality. The average mortality of right and left colon operations at the Mayo Clinic in the past two or three years has been about 10 per cent.

Shedden¹⁹ has collected from the literature thirty-six cases of cancer of the rectum and sigmoid in individuals under twenty years of age, and twenty-four cases between the ages twenty and thirty-five. Two cases were nine years of age. The thirty-six cases included seventeen reported by Phifer and twelve by Bernoulli, together with six other scattered ones, one of which was a Massachusetts General Hospital case. Of interest was the fact that in these young people abdominal symptoms were more prominent than the classical rectal ones, abdominal pain being most prominent. In general, the younger the patient the higher the degree of malignancy. A further analysis of the cases from various standpoints was carried out, and radical operation advocated in these as in adult cases, whenever possible. Biopsy for diagnosis is always advisable.

Gordon-Watson²⁰, reviewing his experience of 200 applications of radium for carcinoma of the rectum and anus, over a seven-year period, concluded that radium may be of some use in rendering operable an otherwise inoperable growth within the rectum, but that a radical operation should be performed whenever there is a reasonable chance of success. In localized epithelioma of the anus he feels that radium treatment has a definite place. The general feeling among men doing this work in our locality is that the degree and duration of pain from radium treatment of lesions in close proximity to the anal sphincter is so great that it has been abandoned in favor of surgical removal.

PECTENOSIS

Abel²¹ gives a detailed and interesting sketch of the anatomy and physiology of the anal canal with particular reference to the small area lying between the true skin and the mucous membrane, and known as the pecten. This area is covered with transitional epithelium, and is the level at which there occurs, in some people, a progressive subepithelial fibrosis which produces a narrow "wedding ring" contraction known as a pecten band, and creates a condition to which the term pectenosis was first applied by W E Miles in 1918. This condition may exist alone, as a progressive contraction, but is often associated with fissure. The operation of pectenotomy consists in dividing this band in the right posterior quadrant, a procedure destined to provide relief of the resulting obstinate constipation, and to bring about healing of a fissure if present. For some reason the band does not seem to reform, as one would expect. The end result of the operation is a very normal anal outlet and a return of normal defecation.

AMEBIASIS

Interest in this disease has received new stimulus as a result of the epidemic in Chicago during the summer of 1933, and as would be expected there have appeared various reports of cases in scattered localities as an aftermath of this epidemic.

Bundesen, Rawlings, and Fishbein²² described the Chicago situation with a report of 185 cases, nineteen deaths, and 193 carriers of *Endamoeba histolytica* detected from August to November, 1933. They emphasize the mildness of symptomatology in some cases, the persistence of the amoebae for long periods of time in carriers, necessitating careful isolation and repeated routine check-ups by stool culture. Organisms may disappear only to reappear after some months. Two of the carriers had been proved as such in a previous epidemic in 1927. The authors also point out that the disease is present constantly even in the more northern zones, as shown by a survey in 1929 by Williams and Geiger who found twenty-seven carriers and two active infections among 148 food handlers studied.

A comprehensive review²³ of the disease in respect to etiology, symptoms, and diagnosis and treatment appeared in the same number of the J A M A.

Charles C Lund²⁴ reported four fatal cases among a group of six lumbermen who were members of a committee at a convention in Chicago. In only one was specific therapy given and even then the diagnosis was made too late to prevent a fatal issue. All lived in different parts of the country. Two were operated upon with a diagnosis of appendicitis.

A fatal case was reported by Scannell²⁵ from Boston, operated upon with x-ray diagnosis of carcinoma of colon.

McKittrick²⁶ reported a case with liver abscess diagnosed by him about six months after exposure to infection in Chicago, and previously operated upon elsewhere with drainage of a subphrenic abscess of undetermined origin.

Ikeda²⁷ presents careful observations on nine cases picked up in one hospital in St Paul, and all traceable to Chicago. He emphasizes the variety of symptoms and difficulty of laboratory diagnosis.

VENEREAL INFECTIONS

Rosser²⁸ has discussed this subject in a concise but thorough manner. He finds primary chancre of the anus rather uncommon, but has seen three cases, shallow ulcers at the anal margin, one with condylomata overgrowing it. He quotes Martin as having reported twenty proved cases. Mucous patches do occur in the rectum in secondary syphilis, but tertiary lesions are quite uncommon. Chancroid occurs with reasonable frequency, usually as multiple lesions. Rosser had seen ten cases since 1925. Gonorrhea is

quite common, especially in the female, and is prolonged as a cryptitis. Irrigations as in urethritis, and ablation of the crypts after the acute stage, will usually clear up the infection.

CHRONIC ULCERATIVE COLITIS

The etiology of idiopathic or chronic ulcerative colitis is still decidedly unsettled. Borgen with Buie²⁹, presents further evidence in support of his conviction that the diplostreptococcus described by him several years ago is a factor in the production of most cases of this disease. His figures and methods are impressive. He reports the isolation of 815 strains of the organism from 1100 patients with the disease. Into 1000 rabbits were injected 500 strains producing lesions resembling the disease in man in 65 per cent of the rabbits. He has isolated the organism from blood culture in eight patients who were seriously ill with the disease. In addition, the organism has been recovered from periapical dental abscesses in 148 of the patients and injected into rabbits in each instance, reproducing the disease in 75 per cent of the animals. Further experiments of similar nature are outlined together with a detailed description of the protoscopic and microscopic picture at different stages in the disease.

Paulson³⁰ strenuously challenges Borgen's work on the basis of bacteriological criteria. He feels that Borgen's diplococci are not a definite organism but rather a phase in the development of many types of chain streptococci. In brief, Paulson feels that the disease is still "idiopathic," that *B. dysenteriae* may play a part in the etiology, and that the cocci in the colon probably are concerned in secondary infection of the ulcers. He emphasizes the inevitable recurrences in most cases, under any mode of treatment, the lack of any specific therapy, and urges that ileostomy, when indicated, be performed earlier than is often the custom. Primarily, however, the disease is a problem for careful medical treatment.

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL PATHOLOGIC EXERCISES

EDITED BY RICHARD C CABOT, M.D.

F M PAINTER, A B, ASSISTANT EDITOR

CASE 20231

PRESENTATION OF CASE

A sixty-eight year old New England farmer entered the hospital complaining of swelling of both legs and indigestion of ten days' duration.

The patient had been well until a year before admission, when he gradually began to lose weight in spite of a good appetite and restful sleep. Five weeks before entry he noticed gradual development of diarrhea associated with severe abdominal cramps. He had about eight bowel movements on the first day. The diarrhea was not watery but merely soft unformed light-colored stools. There was no blood or mucus. With the onset of the diarrhea he suddenly became aware of the fact that his eyes and skin were yellow. This color did not increase in intensity and was not associated with itching. At the same time he noticed that his urine was mahogany colored. About ten days before entry a physician gave him some pills and other medicines which stopped his diarrhea and changed the color of his stools from a very light color to dark purplish black. At that time he began to have "stomach trouble" characterized by constant fullness in his stomach and vomiting every night. The vomitus consisted of recently eaten food but no blood. The color was that of grape juice and had no relation to the type of food. He vomited about five times the night before admission. With the onset of fullness in his stomach he noticed swelling of his legs, more on the left than the right. The swelling gradually rose toward the knees and for the past three days had reached the hips and abdomen. There was no swelling of the arms or face. For the past three or four days he had had hiccups. He had lost about thirty pounds in the past year. His strength had been very good. He had been working until six days before entry. X-rays had been taken by his physician three weeks before entry and were negative.

His past, family and marital histories are all negative.

Physical examination showed an emaciated man with marked jaundice of the skin and sclerae. There were many small purpuric spots over the abdomen and legs. The heart was slightly enlarged to the left. The sounds were

of fair quality. There was a soft systolic murmur at the apex and a harsh systolic murmur along the left border of the sternum. There was an occasional extrasystole. The blood pressure was 140/75. The lungs were resonant and contained many coarse râles scattered over both chests. The abdomen was markedly distended and tense. There was dullness in the flanks and low in the abdomen, elsewhere the abdomen was very tympanitic. The liver edge was palpable at the level of the umbilicus and very slightly tender. Because of the distention it was impossible to determine the presence or absence of irregularities. The spleen was not felt. There was marked edema of the feet, legs, genitalia, lower abdominal wall and lower back.

The temperature was 99.1°, the pulse 86, the respiration 28.

Examination of the urine showed a specific gravity of 1.016. There was a very slight trace of albumin and a four plus bile test. There were occasional hyaline and granular casts and a very rare white blood cell and red blood cell. The blood showed a red cell count of 4,000,000, a hemoglobin of 70 per cent, a white cell count of 26,000, with 94 per cent polymorphonuclears. The stools were soft, formed, brown, alkaline, and showed a four plus guaiac and a positive bile test. The Hinton test was negative. The icteric index was approximately 75, the van den Bergh 13.4 milligrams.

A gastro-intestinal series was done with considerable difficulty due to the weakened condition of the patient and the presence of ascites and fluid in the chest. During the examination of the esophagus, stomach and duodenum, the esophagus was never emptied of barium, apparently because of reflux from the stomach and a small diaphragmatic hernia. The rugae of the esophagus could not be satisfactorily examined, but on one or two of the films there were filling defects which simulated dilated veins. There was no evidence of malignancy in the esophagus, stomach or duodenum. The duodenal loop was not unusually large and there was very little evidence of enlargement of the liver, but the stomach seemed displaced toward the right by a mass in the region of the spleen. The splenic flexure, however, was moderately high in position. The hepatic flexure was in normal position. Several diverticula were seen in the region of the sigmoid. The mucosa of the colon appeared normal.

The patient was put on a high carbohydrate diet with fluids. Several abdominal taps were performed. The ascitic fluid had a specific gravity of 1.009 and contained 200 red blood cells, 1300 white blood cells and about 160 epithelial cells. Three days following admission he had a frank hemorrhage from the stomach. The ascites reaccumulated. It was believed that he

was being helped by intravenous glucose. On the ninth day he was transfused with 450 cubic centimeters of whole blood and four days later with 325 cubic centimeters. On the fourteenth day he vomited a little blood and passed a tarry stool. An abdominal paracentesis was done that day with the removal of two liters of deep yellow fluid. This was followed by an injection of four cubic centimeters of salyrgan intra-peritoneally. Three days later 4000 cubic centimeters of ascitic fluid was removed. A surgical consultant did not believe operation was advisable. On the twenty-first day a narrow elongated mass was felt just above the umbilicus. It was not determined whether this mass was in the abdomen or in the abdominal wall. He continued to receive intravenous glucose but he gradually failed, vomiting small amounts of blood from time to time. The cord-like mass in the epigastrium was more prominent during the last few days of life. He died twenty-four days after admission.

X-RAY INTERPRETATION

DR AUBREY O HAMPTON We had difficulty in examining this patient. The thing we tried to decide was whether or not he had carcinoma of the gastro-intestinal tract, cirrhosis of the liver or cancer of the liver.

We had some evidence that the spleen might be enlarged at the examination of the stomach. There is an area in here which seems to be larger than usual. The fundus of the stomach is small and certainly not displaced toward the left, perhaps displaced toward the right. When we filled the colon, however, the splenic flexure occupied that space, and yet there is no gas at this examination. So that we had about a fifty-fifty chance of saying whether the spleen was normal or abnormal.

We found diverticula in the colon spasm of the sigmoid and a generally dilated colon which contained gas and a moderate amount of feces.

That was all we found, no evidence of cancer in the colon or stomach.

Then we tried to examine the esophagus with special reference to the mucosa and varicose veins but here again we had this shadow which seemed to displace the fundus of the stomach to the right, a hernia of the stomach and an esophagus that did not empty at all. We gave him a drink and it stayed there, part of it in the fundus but at least the lower half of the esophagus would stay filled so we had no opportunity to examine the mucosa.

We found a diverticulum in the middle third of the esophagus that was not in the note but does not amount to anything—a traction diverticulum. Here is the diverticulum in relation to the arch of the aorta. The diaphragm is quite high, with fluid on both sides of the pleural

cavity, and the part of the esophagus we wanted to examine was obscured by fluid, by the diaphragm and by barium.

DR WYMAN RICHARDSON Was there any fluid in the chest?

DR HAMPTON Yes. This film shows a little distortion but it is present in one of the films we have here. Dr Schatzki came over to help me find varices of the esophagus but he gave it up too. There is a long shadow that looks a little like a varix. We finally decided we could not make a diagnosis of cirrhosis of the liver. All that we could say was that he had diverticulitis, diaphragmatic hernia, diverticulum of the esophagus, pleural effusion and high diaphragm.

DIFFERENTIAL DIAGNOSIS

DR RICHARDSON This is a very definite clinical story with progression to the inevitable ending, death. It should have a very definite answer to it but when we come to consider the possibilities it does not appear so clear as I should like to have it. The things we have to explain in the order of occurrence are weight loss, diarrhea, jaundice, edema, vomiting, hematemesis, leukocytosis and death.

The weight loss is definite according to the history, for a period of a year, and suggests definitely some systemic disturbance. There was no change in the man's habits. He was known to eat well. I think we must assume that he has had systemic disturbance for a year. I am thinking of neoplasm and cirrhosis of the liver.

Diarrhea which began five weeks before admission to the hospital, was coincident with a jaundice which apparently was obstructive in type, or largely obstructive. I explain the diarrhea on the basis of some disturbance in the digestion particularly undigested fat and particularly as associated with the jaundice. It should be noted that one brown stool was seen in the hospital here and gave a positive test for bile, but the description of that jaundice seems to me very definitely obstructive.

Edema appeared. It is a curious edema, starting in the left foot gradually involving both feet and resulting in ascites. Although there was no clinical evidence of fluid in the chest there is some x-ray evidence of it. That edema cannot be due to cardiac disease or renal disease. So far as I can see, it must therefore be explained either on the basis of cirrhosis or some severe damage to the liver, or on the basis of some obstruction of the venous return.

The vomiting I believe, was due to venous stasis with impaired gastric function. This was followed by the vomiting of blood, and again I think it was due to venous stasis. There may have been some gastritis, but I think no definitely ulcerative lesion will be demonstrated.

The leukocytosis should be explained, and I cannot explain it. Twenty-six thousand is a high count. I should like to have seen the smear with regard to whether there were any abnormal cells or whether the white cells were toxic, of the type seen in infection.

Finally he died. Did he die of hepatic failure? Did he die of hemorrhage? Or did he die of some gastro-intestinal disturbance such as an ileus, as the result again of venous stasis? I think he died of all three factors.

In differential diagnosis, then, the things that come up are first cirrhosis of the liver. This is an extraordinarily rapid progression for portal cirrhosis. The jaundice is intense and severe, rather sudden, and does not suggest the mild jaundice seen in portal cirrhosis. The liver is said to be big. We can possibly doubt that, as the difficulty of palpating the liver in an ascitic abdomen is very great. We shall have to assume something besides pure cirrhosis of the liver. I think some degenerative lesion in addition to a cirrhosis which was previously present might explain the symptoms. I mean he might have a subacute yellow atrophy on top of an already damaged liver that might conceivably give this picture. Edema as the first symptom of cirrhosis of the liver is a very serious sign, but the whole story here, with marked and sudden edema, does not suggest to me subacute yellow atrophy on top of cirrhosis of the liver, although this possibility should be borne in mind. There is no history of the ingestion of any toxic material. This was the only condition that I considered other than the one I have suggested for a definite diagnosis.

I believe that this man had a venous obstruction somewhere high in the abdomen, probably associated with some sort of venous thrombosis and surely involving the portal system. I think too that he has a definite malignant lesion of some sort, some part of which will be found to involve the biliary tract. Finally I think he has aortic arteriosclerosis, simply on the basis of the harsh systolic murmur heard at the base of the heart.

CLINICAL DISCUSSION

DR TRACY B. MALLORY: Dr. Jones, you had the advantage of seeing this patient.

DR CHESTER M. JONES: I went through the same mental difficulties that Dr. Richardson has and finally arrived at a diagnosis, but I do not think I did so well as he. From the story there are only two possibilities, either cirrhosis with subacute atrophy, which clinically fitted the picture very well, or malignancy. More or less arbitrarily we decided that cancer offered no opportunity for treatment, therefore the only optimistic point of view was the possibility of cirrhosis with acute yellow atrophy and to treat

the patient as if he had that. That we did. For a short time,—a week or ten days,—he improved very definitely under fairly energetic treatment for very severe liver damage.

The ascites, pleural effusion, edema, all could be explained on the basis of hepatic failure. It seemed to me, because it very frequently does occur either with cirrhosis alone or cirrhosis plus acute yellow atrophy.

There were one or two findings of extreme interest. One was the finding of a good deal of blood in the stools. One also can get a strongly positive guaiac in any severe liver injury whether due to intrahepatic disease or with disease due to a lesion of the bowel. It is a little more suggestive of malignancy than of intrahepatic disease. One other finding of some interest—and I have the advantage of Dr. Richardson in that—was the color of his stools. He did have several stools that contained plenty of bile. They became more bile stained during the first few days. There were several days when there was a good quantity of bile, a point somewhat against cancer, and it was possible that there again we were dealing with an intrahepatic jaundice rather than with one due to pure obstruction from outside.

The question as to whether there was or was not a spleen was an important one to decide, and we were not able to decide it. The evidence we had seemed more in favor of large spleen than not. There were several x-ray findings. In the presence of such a picture in most instances it is safe to say that splenomegaly is direct evidence against malignancy and strongly in favor of intrahepatic disease. I always try to make a very definite effort to convince myself whether or not there is a large spleen. In this case we were not able to make a positive finding, although the evidence was in favor of some splenic enlargement.

We felt right along, and told the family also that he had one of two things, either cancer or some sort of intrahepatic disease, probably on the basis of an old cirrhosis. I have forgotten whether the final picture was one of a terminal hemorrhage.

There was one finding we overlooked, and as Dr. Richardson read the history it was very easy to overlook. It did not strike us as an important finding, but it should have given us the clue to the diagnosis. That was the appearance of a mass in the abdominal wall about an inch across in the vicinity of the transverse colon. At first we wondered if there was any fecal material in the transverse colon. It developed very rapidly, in a week or ten days, and toward the end it became evident that it was just under the skin.

I have forgotten what diagnosis he was discharged with, but I certainly hesitated between the two diagnoses of cancer or atrophy on top of

cirrhosis, realizing that malignancy had to be considered very strongly

CLINICAL DIAGNOSIS

Acute yellow atrophy (on old cirrhosis of the liver)

ANATOMIC DIAGNOSES

Carcinoma of intrahepatic bile ducts with metastases to the gall bladder

Acute atrophy of the liver

Jaundice

Ascites

Chronic cholecystitis

Cholelithiasis

Chronic fibrous peritonitis

Perisplenitis

Arteriolar sclerosis, slight renal

PATHOLOGIC DISCUSSION

DR MALLORY The autopsy findings here showed a rather small liver which was not nodular and on the outside except for discoloration from bile stasis, seemed practically negative but when we cut into it we found that the major portion of the right lobe was replaced by a mass of obvious carcinoma. This was apparently primary in the right hepatic duct just inside the liver and had spread up the periportal spaces following the ramifications of the bile ducts throughout much of the right lobe of the liver. A few strands of tumor were found in lymphatics in the gall bladder wall, but the mucosa of the gall bladder was not involved. So that I feel quite sure it is a primary carcinoma of the intrahepatic bile ducts.

There was also very extensive necrosis of the liver tissue most marked in the immediate neighborhood but also extending throughout the entire liver. So for once we can agree with both parties. There was a considerable degree of atrophy and there was malignancy.

The mass which was felt in the abdominal wall was a peritoneal implant of the tumor on the peritoneal surface of the anterior abdominal wall tying it to the transverse colon. There were widespread peritoneal implants throughout the entire cavity and I should imagine that the ascites was directly due to them that is, a cancerous peritonitis rather than obstructive from the liver itself.

The venae cavae appeared slightly dilated but were free from thrombi, and we found no thrombi in the iliac vessels.

A STUDENT Was there any fluid in the chest?

DR MALLORY We were restricted to the abdomen. We did not examine the chest.

DR HAMPTON How big was the spleen?

DR MALLORY The spleen was extremely small weighing only 75 grams, and I cannot explain the distortion.

DR HAMPTON The small liver might cause the stomach to move to the right.

DR ARLIE V BOCK Was there a diaphragmatic hernia?

DR MALLORY That was not particularly obvious and we did not know that x-ray report at the time and missed it. I think it is very easy to miss a diaphragmatic hernia unless our attention is called to it.

DR HAMPTON We have had the same thing come up before, displacement of the stomach due to large liver. I do not understand why the spleen does not enlarge if the liver is small though.

DR MALLORY With cirrhosis the spleen almost invariably enlarges.

DR HAMPTON I think Dr Schatzki has seen one patient with varices in the esophagus due to carcinoma.

DR RICHARD SCHATZKI One case, not malignancy of the liver but malignancy of the stomach with glands surrounding the portal vein at its entrance to the liver giving portal obstruction.

DR MALLORY In this case we were unable to demonstrate any varices in the stomach, also we were unable to find any hemorrhoids. We did not find any definite focus to account for the bleeding either by mouth or by rectum.

DR JONES Was he jaundiced enough so that he could have had a diffuse mucous membrane bleeding?

DR MALLORY Yes.

DR JONES I should like to ask one question. I think it is a very important diagnostic point in handling these cases as to whether there is, or is not an enlarged spleen. I have made it a working rule that if the spleen is enlarged it is against malignancy. I should like to know what Dr McKittrick and Dr Bock think of that as a working rule.

DR LELAND S MCKITTRICK A palpable spleen due to cancer is exceedingly rare. Dr Jones's point is very well taken.

DR BOCK That is a somewhat difficult question. If the liver is enlarged and the spleen is not palpable the chances are great that one is dealing with a cancer of the liver as opposed to a cirrhotic process.

DR RICHARDSON How about the leukocytosis?

DR JONES I think that was very remarkable. I could not explain it at the time. I have forgotten whether subsequent counts were high or not. I think at times one does get a leukocytosis in acute yellow atrophy but I am not absolutely certain of that. I do not think it follows the general rule that in severe liver disease one gets a leukopenia.

DR MALLORY Certainly in some cases you find an enormous infiltration of the liver with polymorphonuclears which would almost necessitate leukocytosis.

A PHYSICIAN How often do you get an en-

larged spleen at autopsy that is not felt some-time before death?

DR MALLORY Fairly often

CASE 20232

PRESENTATION OF CASE

First admission A thirty-seven year old American postoffice clerk entered for the first time fifteen years before his fifth and last admission

He had been seen in the Outpatient Department for six years for ulceration of several of his toes. Although his Wassermann was negative at the beginning of his Outpatient treatment he was given salvarsan, and four years later was given potassium iodide and mercury at another hospital. His right fifth toe was amputated. During his first stay in the Massachusetts General Hospital his Wassermann was strongly positive. He was discharged at the end of nine days with a diagnosis of syphilitic endarteritis.

Second admission, twelve years later

During his stay the second and third right toes were amputated for bone necrosis. A Hinton test was negative. He was discharged at the end of a month.

History of interval Ten and a half months after his discharge he had a gastric upset with considerable gas, nausea and slight vomiting. There was no blood in the vomitus, and no pain. About ten days before his third admission the calloused area became ulcerated and a few days later the whole foot became swollen, red and hot.

Third admission, a year after his previous discharge

X-ray examination showed spina bifida of the sacral segments. Operation upon the leg was not felt to be indicated. He was discharged in two weeks somewhat improved.

Fourth admission, a year and a half later. The complaint at this time was return of the old pain in his right foot and leg.

He gave a history of having had a chronic mild cough for five or six years. The cough would occur about every ten minutes with the production of a white watery sputum amounting to about a cupful a day. The sputum was not foul smelling. There were no hemoptyses or night sweats.

Examination showed a pale, pasty faced man lying apathetic in bed. The left pupil was larger than the right and both were somewhat irregular. Both lungs were filled with coarse moist and sibilant râles. There were trophic ulcers of both feet. There was no evidence by x-ray of bone destruction or new bone formation.

The lesions on his feet were treated with

poultices and boric packs. He was discharged in five days improved.

History of interval Six months later, four months before his fifth admission, he began to have a poor appetite. He did not have any gas, nausea or vomiting between meals. Three weeks before admission he began to have epigastric discomfort between meals. The day before admission while riding to work he suddenly felt a sharp pain in both shoulders and had severe nausea. He went directly to the dispensary in the postoffice where he worked, and there collapsed. After vomiting his breakfast he continued to bring up brownish material which his physician called blood. He remained at home that day and continued to have severe pain in his shoulders. He noticed that his abdomen was beginning to be distended. His last bowel movement occurred the morning before admission. He was brought to the Emergency Ward by ambulance.

Fifth admission, ten months after his fourth discharge.

Physical examination showed a pale, emaciated middle aged man. The skin was moist. The mucous membranes were pale. There was slight stiffness of the neck on flexion and lateral movements. The chest showed a costal type of breathing. There were no diaphragmatic movements. The heart sounds were of fair quality. The blood pressure was 128/108. The abdomen was scaphoid and showed marked muscle spasm. It was tympanic throughout and showed some shifting dullness and some obliterated liver dullness. There was no tenderness.

The temperature was 101.2°. The Hinton test was positive, the Wassermann negative.

An x-ray film taken with the patient prone showed a normal kidney outline on the right. The left kidney was obscured by an artefact. When the patient assumed the upright position a large amount of gas was visualized beneath the diaphragm on both sides.

He was operated upon immediately. He failed very rapidly and died approximately an hour and a half after the operation.

DIFFERENTIAL DIAGNOSIS

DR BETH VINCENT It will occur to all of us after listening to this history that a perfectly logical diagnosis can be made which seems to be fairly consistent with the data given in this case. In fact it fits so well that my experience in these exercises makes me doubt the accuracy of the diagnosis. But I think we must analyze these cases and evaluate the facts as they are given.

This man was in the thirties and had been under observation in this hospital and others at various times since he was fifteen years old. He finally came in after an acute attack of apparently two days' duration. We will begin by

analyzing that attack and then see if the past history that we have available will throw any light on the condition for which he underwent an operation

He was pretty well, because he was going to work, and then he was suddenly taken with a sharp pain in both shoulders and severe nausea. We are not told whether he had pain in the abdomen. He collapsed, was taken to a dispensary, stayed there for a while and went home. He continued to vomit and was brought to the hospital in an ambulance, I take it the next morning, apparently a very sick man at that time.

When he reached the hospital they found that he was very much emaciated. I will select the things that seem of value in this attempt at diagnosis. There is slight stiffness of the neck, a costal type of breathing and a scaphoid abdomen with marked muscular spasm. For the first time we begin to suspect that this was an acute abdominal condition with which we were dealing. Inconsistent with this, however, is the fact that he had no tenderness. Going farther we find that there was shifting dullness indicating fluid, an observation by the way which in my experience is very apt to be wrong both ways. Sometimes there is free fluid in the abdomen and we are unable to detect it on physical examination, and quite frequently we demonstrate free fluid that proves not to be there when we open the abdomen. Therefore we will take this for what it is worth. He has free fluid the abdomen is tympanitic with some shifting dullness and some obliterated liver dullness. The x-ray shows that there was a large amount of gas visualized beneath the diaphragm on both sides. Here is a very definite physical fact that we have to count on and to account for. He also had a temperature.

I think he underwent an emergency operation. The question is what were the findings? I should suspect that they would find a peritonitis. I should suspect that the peritonitis was due to perforation somewhere along the alimentary tract. The next thing is to go over the case again and see if that diagnosis is correct and go farther and determine the character of the lesion which caused the perforation.

The fact that he had pain in the shoulders, if this is an abdominal case, would indicate that the lesion was above the umbilicus rather than below, because we know that abdominal pain high up is frequently referred to the shoulders. In the absence of any definite statement we will assume that it was an upper abdominal lesion.

What are the forms of perforation that we most commonly deal with surgically? If it is in the lower abdomen we sometimes have rupture of an enlarged cecum. The cecum is enlarged usually because we have obstruction on the left side, due often to a scirrhus cancer of the sigmoid. We have nothing, however, to indi-

cate that the man was obstructed or had scirrhus cancer. He would not necessarily have blood in the movements. He had not the lower abdominal tenderness that we find in these cases that eventually have a ruptured cecum from distention and necrosis.

In the upper abdomen of course the things that most often cause perforation are rupture of a peptic ulcer, gastric or duodenal or rupture of a malignant ulcer of the stomach. He had a poor appetite for several months before his entry this time. He began to have some pain between meals, which looks more like a peptic ulcer. He was emaciated when he came in, which of course would be consistent with cancer. He had the collapse with sudden onset that we see more often in rupture of an anterior wall duodenal ulcer than from any other cause. I should think so far as frequency goes it is more apt to be duodenal ulcer than anything else although it might be cancer of the stomach.

Going into the past history to see if there is any information there to help us we find that as a young person he came under observation for ulceration of his toes and was later found by x-ray to have spina bifida so he probably had trophic ulcers. The Wassermann was negative at his first visit, but later it was positive. In all probability he had acquired syphilis in the meantime. I think we may assume that he had syphilis. I am at a loss to describe any syphilitic lesion of the abdomen that would give this picture of perforation. Gastric syphilis could I suppose give rise to an ulceration and perforation but syphilis of the stomach usually results in fibrosis and deformity. People with syphilis of the stomach get very thin but have a good appetite. This man had no appetite. I am unable to suggest any syphilitic lesion with the account of this abdominal emergency.

I prefer to come to the conclusion that he did have a perforation of the alimentary tract, and as we have nothing to indicate that it took place in the esophagus that it probably was a lesion in the upper abdomen. It could be due either to malignancy of the stomach or to gastric or duodenal ulcer. Duodenal ulcer being more common, I think I will say that he had peritonitis with perforation from duodenal ulcer.

CLINICAL DISCUSSION

DR JAMES C. WHITE. We had this patient on the Circulatory Service several times. He had two types of known spinal disease to account for trophic ulcers of the type that he had had, central nervous system lues and spina bifida, both very common causes of the type of ulcer that he showed. If he had been a diabetic he might also have had very similar looking ulcers. These are the three most common causes of trophic ulcers that we have seen on the

Peripheral Vascular Service It was very hard for us to decide which type of etiology was the cause of this ulceration at the time we saw him, although Dr Vincent has pointed out that he probably had ulcers before he acquired syphilis, so that the primary cause must have been his spina bifida

In treating him we amputated several toes. As in all these cases with trophic ulcer of spinal cord origin, there was no difficulty in healing. As both his legs were involved, it was very difficult to give him a good working leg. I cannot remember the anesthetic level, but the reason we could not do any adequate weight bearing amputation was because his anesthesia extended so high. We therefore had to carry him along in a palliative way and keep his feet in the best possible condition.

I did not see him at the final admission.

Dr W. Jason Minter I do not think I have anything to add to what Dr White has suggested. Here is a man who has spina bifida and who has lues. I should be more tempted to place the ulceration on the basis of his spina bifida than on the lues.

The question of operating on the spina bifida at an earlier date might be brought up. Some of these people have been operated on with some improvement, but the general run of them do not improve greatly after operation when the picture is as complicated as in this instance.

CLINICAL DIAGNOSES

Perforated duodenal ulcer
Shock, peritonitis, ileus

ANATOMIC DIAGNOSES

Duodenal ulcers, one perforated, one healing
General peritonitis
Pulmonary emphysema
Arteriosclerosis, slight

PATHOLOGIC DISCUSSION

Dr Tracy B. Mallory At the time of an autopsy unfortunately we did not know all this man's story, so we did not make any investigation of the spinal canal. The immediate cause of death was, as Dr Vincent thought, a perforated ulcer of the anterior duodenal wall. There was a generalized peritonitis associated with it. The total amount of fluid present was estimated at 400 cubic centimeters only, so that I doubt if the shifting dullness meant anything. The duodenum also showed a kissing ulcer on the opposite side which had not as yet penetrated very deeply into the muscularis but showed very marked scarring and fibrosis, so that between the two ulcers the duodenum was very markedly narrowed. I think that is a very adequate explanation of his malnutrition.

The rest of the autopsy showed very little that was significant except a pulmonary emphysema of unusual degree for a relatively young man. In ten more years he might well have begun to have symptoms from it.

CRITICISMS OF THE BOSTON CITY HOSPITAL

THE Finance Commission of Boston has made recommendations for a revival of the conduct of the Boston City Hospital as defined in a report to the Mayor and the City Council

Three phases of the administration are criticized relating (1) to the acceptance of chronic cases (2) the treatment of patients who are able to pay for hospitalization and (3) the admission of non-residents of Boston

It is the opinion of the Commission that at least forty-one per cent of the patients are treated in violation of the statute which provides that the hospital was established "for the reception of persons who by misfortune or poverty may require relief during temporary sickness"

The fear that some of the poor people of Boston may be unable to secure admission to the hospital if the present system is maintained is expressed in this report. Although there is no intimation that the poor of Boston have been deprived of the service of the City Hospital to

any great extent, the opinion that "the trustees are not justified in spending the taxpayers' money for the care of persons who are able to care for themselves" is emphasized, and the competition of this hospital with private practitioners is deprecated

While these criticisms have a technical justification according to the statute, it should be recognized that an extensive and important service is rendered to the indigent people of Boston by the staff without any financial recompense and further that the city profits to a great extent by the education of physicians who outside of the hospital walls serve the people of this municipality more efficiently by reason of the opportunities for study and training therein

It is probably impossible to estimate adequately the value of this institution to the city directly and through its contributions to medical education

Boston stands as a great center for advanced research and teaching of medicine and the city reaps a large harvest directly through the great number of people who come here because of this distinction. The reputation of the medical men here tends in no small way to keep Boston in the front rank of progressive cities. They are worthy of recognition in the way of all reasonable opportunities for caring for their patients. Abuses are suspected, and in some instances proved in hospital administrations at times in many places, and should be corrected but fairness to the administration and the medical staff may require a just evaluation of the benefits conferred upon the city as a whole by institutions like the Boston City Hospital. Even with attention to the criticisms of the Commission, may it not be wise to strive for an amendment to the statute enacted to create the City Hospital in order that there shall be no weakening of its beneficent functions toward its patients and no interference with scientific progress?

Changes are taking place throughout the world as efforts are being made to adjust modern agencies to present-day problems, and since hospitals have contributed in large measure to medical education, a broad conception of hospital functions should underlie all attempts at reform. Dollars and cents should not obscure the great objective

THE HANDICAPPED

THE last issue for 1933 of *The Commonwealth*, the quarterly publication of the Massachusetts Department of Public Health concerns itself with the problems of the handicapped, composing in effect a symposium on the organized efforts which are being made to help this class of individuals. The handicapped, broadly defined are those who for a variety of reasons physi-

Peripheral Vascular Service It was very hard for us to decide which type of etiology was the cause of this ulceration at the time we saw him, although Dr Vincent has pointed out that he probably had ulcers before he acquired syphilis, so that the primary cause must have been his spina bifida

CRITICISMS OF THE BOSTON CITY HOSPITAL

THE Finance Commission of Boston has made recommendations for a revival of the conduct of the Boston City Hospital as defined in a report to the Mayor and the City Council

Three phases of the administration are criticised relating (1) to the acceptance of chronic cases (2) the treatment of patients who are able to pay for hospitalization and (3) the admission of non-residents of Boston

It is the opinion of the Commission that at least forty-one per cent of the patients are treated in violation of the statute which provides that the hospital was established "for the reception of persons who, by misfortune or poverty may require relief during temporary sickness"

The fear that some of the poor people of Boston may be unable to secure admission to the hospital if the present system is maintained, is expressed in this report. Although there is no intimation that the poor of Boston have been deprived of the service of the City Hospital to

any great extent, the opinion that "the trustees are not justified in spending the taxpayers' money for the care of persons who are able to care for themselves" is emphasized, and the competition of this hospital with private practitioners is deprecated

While these criticisms have a technical justification according to the statute, it should be recognized that an extensive and important service is rendered to the indigent people of Boston by the staff without any financial recompense, and further that the city profits to a great extent by the education of physicians who outside of the hospital walls serve the people of this municipality more efficiently by reason of the opportunities for study and training therein

It is probably impossible to estimate adequately the value of this institution to the city directly and through its contributions to medical education

Boston stands as a great center for advanced research and teaching of medicine and the city reaps a large harvest directly through the great number of people who come here because of this distinction. The reputation of the medical men here tends in no small way to keep Boston in the front rank of progressive cities. They are worthy of recognition in the way of all reasonable opportunities for caring for their patients. Abuses are suspected, and in some instances proved in hospital administrations at times in many places, and should be corrected, but fairness to the administration and the medical staff may require a just evaluation of the benefits conferred upon the city as a whole by institutions like the Boston City Hospital. Even with attention to the criticisms of the Commission, may it not be wise to strive for an amendment to the statute enacted to create the City Hospital in order that there shall be no weakening of its beneficent functions toward its patients and no interference with scientific progress?

Changes are taking place throughout the world as efforts are being made to adjust modern agencies to present day problems, and since hospitals have contributed in large measure to medical education, a broad conception of hospital functions should underlie all attempts at reform. Dollars and cents should not obscure the great objective

THE HANDICAPPED

THE last issue for 1933 of *The Commonwealth*, the quarterly publication of the Massachusetts Department of Public Health, concerns itself with the problems of the handicapped, composing, in effect a symposium on the organized efforts which are being made to help this class of individuals. The handicapped, broadly defined, are those who for a variety of reasons, phys-

cal or mental, lack the equipment to meet life in open competition with their fellows. Their needs and the methods of filling them are outlined here by experts in their various fields. Thus, Eleanor E. Kelley, Supervisor of Social Service of the Department of Public Health explains what the social worker can do for the handicapped in the way of determining the type, extent and duration of the handicap and the necessary adjustments to it. Agnes Early, formerly Community Nutritionist of Lawrence, outlines the nutrition program which worked out so successfully in that city. Dr. T. Duckett Jones of the House of the Good Samaritan, explains the care of cardiac children. Caroline N. Shaw, Director of Occupational Therapy of the Robert B. Brigham Hospital, contributes a paper on occupational therapy. Dr. Leon A. Allen, Superintendent of the Lakeville Sanatorium, writes on vocational guidance for the tuberculous child. Bernice W. Billings and Esther L. Trutkoff explain the object and methods of the Sheltered Workshop of the Boston Tuberculosis Association in providing training and suitable employment for patients who have been treated for tuberculosis in sanatoria or at home and have become well enough to work but are not yet strong enough to return to full-time jobs.

Somewhat the same type of help is being given by the Cooperative Workrooms, Inc., as described by Hazel Newton. Dr. Neil A. Davton, Director of the Division of Mental Deficiency of the Department of Mental Diseases, describes the traveling school clinics for the examination of retarded children in the public schools. Dr. L. Vernon Briggs writes on the prevention of crime. Anna King, Director of Social Service of the Austen Riggs Foundation, contributes an article on the maladjusted school child and his needs. Further papers are on the rest and nutrition program in the Boston Public Schools, by Dr. Clara Lortman, physical education for the handicapped, by Carl L. Schrader, of the Department of Education, vocational rehabilitation for disabled persons, by Robert O. Small, of the same Department, atypical children and their education, by Arthur B. Lord, Supervisor of Special Schools and Classes of the Department of Education, the program and its results of the Massachusetts Hospital School, by Ruth Park, and the annual census of physically handicapped children, by Margaret MacDonald, of the Department of Public Welfare. The introductory article on community care of the handicapped is contributed by Mr. Herbert C. Parsons, Executive Secretary of the Massachusetts Child Labor Committee.

The Commonwealth always furnishes valuable and stimulating reading, the number under discussion is particularly instructive, and the editor, Dr. M. Louise Diez, Director of the Division of Child Hygiene, deserves both congratulations and the heartiest support in this undertaking.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

DAVIS, LINCOLN B.A., M.D. Harvard University Medical School 1898 F.A.C.S. Formerly, Chief of East Surgical Service, Massachusetts General Hospital. Now, President, Boston Medical Library. Consulting Surgeon, Massachusetts General Hospital. His subject is "The Objectives of Medical Progress." Page 1197. Address 279 Beacon Street, Boston, Massachusetts.

MYERSON, ABRAHAM M.D. Tufts College Medical School 1908. Professor of Neurology, Tufts College Medical School. Director of Research, Boston State Hospital. Visiting Neurologist, Boston City, Beth Israel and Bickur Cholim Hospitals. Address 270 Commonwealth Avenue, Boston, Massachusetts. Associated with him is

BERLIN, DAVID D. M.D. Tufts College Medical School 1923 F.A.C.S. Assistant Professor of Anatomy, Tufts College Medical School. Surgeon to Thyroid Clinic, Beth Israel Hospital. Assistant to Visiting Surgeon, Boston City Hospital. Address 68 Bay State Road, Boston, Massachusetts. Their subject is "A Case of Postencephalitic Parkinson's Disease Treated by Total Thyroidectomy." Page 1205.

MISCELLANY

THE NORFOLK DISTRICT MEDICAL SOCIETY

OFFICIAL COPY OF ACCEPTED RESOLUTIONS OF THE RESOLUTIONS COMMITTEE

Whereas free and nearly free treatment privileges in municipal and endowed charitable hospitals are designed primarily for the indigent and when properly managed meet with the approval, coöperation and support of the medical profession and

Whereas the growing extension in such institutions of this care and treatment to the non indigent results in a lessened efficiency and a comparative neglect of the deserving people for whom these privileges are established and

Whereas this recognized abuse of such medical charity often results in unwitting and unfair competition with the private physician by these supposedly charitable institutions therefore

Be it resolved that

1 The Norfolk District Medical Society through its Councilors urge upon the Massachusetts Medical Society the need for immediate corrective action to speedily bring relief from the aforesaid existent conditions through appropriate legislation and all other necessary measures

2 The Norfolk District Medical Society through its proper officers and committees bring the matter at once to the attention of His Honor the Mayor of the City of Boston and to the proper authorities of the various charitable hospitals in greater Boston urging that these cited abuses and impositions be discontinued and that every effort be made to correct and eradicate them

3 There be established in Boston by the municipality or by the coöperation of private agencies representative of the charitable hospitals or both a duly accredited agency or clearing house which shall investigate the financial status of all applicants for medical charity, in any and all branches and which shall be empowered to issue suitable and certified

credentials to those found worthy of gratuitous treatment.

4 Pending the establishment of this proposed agency or clearing house, each institution in question be urged to make every effort to expedite the correction of these existing abuses by the signed statement of each applicant in affirmation of the necessity for gratuitous treatment further, to display in such a manner as to be easily read by all applicants for charitable aid, in any and all branches, a suitable sign indicating clearly that the institution, or at least that particular department, is for charity patients only and is not open to those financially able to pay a fee to a physician, and finally, should it be learned at any time that this entrance requirement has been ignored by any applicant, a penalty of the immediate termination of treatment shall be exacted

5 Copies of this resolution be placed in the hands of neighboring district societies with the request that such societies join with the Norfolk District Medical Society in this movement to correct and eradicate the aforesaid abuses of medical charity

Signed

FREDERICK L. HAYES, *Chairman*,
MAURICE GERSTEIN,
DAVID HALBERSLEBEN

April 18 1934

A LIBRARY OF LEGAL MEDICINE

The dedication of the George Burgess Magrath Library of Legal Medicine occurred in the Faculty Club of the Harvard Medical School May 23 1934

This library is named for Dr Magrath, medical examiner of Suffolk County, who is the first occupant of the chair of legal medicine at Harvard established in 1932 by Mrs Francis Gleffner Lee of Littleton N. H. who is also the donor of the new library

The library will have one thousand volumes of rare editions, and it is the intention of the donor that it will be the best collection of literature relating to the specialty extant.

Mrs Lee and Dr Conant, President of Harvard University addressed the meeting

OSTEOPATHS DENIED THE RIGHT TO PRACTICE SURGERY

A bill designed to confer on osteopaths the right to practice surgery within certain limitations in New York State was vetoed by Governor Lehman in the following language

This bill eliminates the present requirement of the Education Law that an osteopath shall not perform surgery with the use of instruments and adds a number of provisions which seem to authorize osteopaths to engage in every form of medical practice except the giving of drugs by mouth to cure disease and the performance of certain specified surgical operations' the Governor said in his veto of the bill

"This bill is objectionable, too, because it contains vague and unintelligible language. The Department of Education states that, because of ambiguous language, it would be impossible to restrict and prevent any type of medical practice other than some types of major surgery.

"Although the proponents of the bill have argued that the intent is that surgical practice be limited to the first aid and minor surgery, no such limitations are explicitly written into the bill."

CANCER HOSPITAL FIFTY YEARS OLD

The Memorial Hospital for the Treatment of Cancer and Allied Diseases, Central Park West and 106th Street, will observe its fiftieth anniversary to night and to-morrow. A scientific meeting will be held to-night at the Academy of Medicine, 2 East 103d Street, with Dr. John A. Hartwell, Dr. Clarence Cook Little, Dr. James B. Murphy, Dr. Robert B. Greenough and Dr. E. C. Dodds, of London, as speakers. Eleven symposia on various types of cancer will be held at the hospital to-morrow with a dinner at the Waldorf Astoria in the evening—*New York Times*, May 24, 1934.

GROUP HOSPITAL INSURANCE

Governor Lehman on May 16, 1934, signed the bill which authorizes the establishment of non-profit group payments for hospital service. In connection with this New York plan, Homer Wickenden explained that the purpose is to provide hospitalization for workers on small salaries through systematic monthly payments with the added provision that workmen desirous of availing themselves of this plan authorize employers to deduct, from their pay, sums amounting to about ten dollars per year for the provision of three weeks' free hospital care of a semi-private nature, by physicians chosen by the patient. This, however, does not include the physician's charges.

Sentiment in favor of such plans seems to be growing, for about six thousand persons in Orange County, New Jersey, are receiving hospitalization under a similar plan.

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR APRIL, 1934

Present indications are that the epidemic of measles reached its peak in March and is now on the decline.

Morbidity from whooping cough had its highest reported figure since 1915.

Diphtheria, pulmonary tuberculosis and tuberculosis other forms reached their lowest reported April incidence.

Typhoid fever is running considerably lower than in 1933.

The incidence of dog bites remains high.

Anterior poliomyelitis, lobar pneumonia epidemic

cerebrospinal meningitis, German measles, mumps, and chicken pox show nothing remarkable.

RARE DISEASES

Anterior poliomyelitis was reported from Lowell, 1. *Dysentery (amebic)* was reported from Cambridge, 1, Worcester, 1, total, 2.

Encephalitis lethargica was reported from Boston, 1, Clinton, 1, Fall River, 1, Lawrence, 1, Marblehead, 1, Marlboro, 1, Springfield, 1, total, 7.

Cerebrospinal meningitis was reported from Boston, 1, Cheshire, 1, Conway, 1, Easthampton, 1, Holyoke, 1, Norwell, 1, Springfield, 2, Worcester, 1, total, 9.

Pellagra was reported from Nahant, 1.

Septic sore throat was reported from Belmont, 1, Boston, 11, Cambridge, 1, Chelsea, 1, Easthampton, 1, Lowell, 1, Revere, 1, Stoneham, 1, total, 18.

Tetanus was reported from Lawrence, 1, Salem, 1, total, 2.

Trachoma was reported from Cambridge, 1, Lawrence, 1, total, 2.

Trichinosis was reported from Longmeadow, 1.

THE SCHOOL OF NURSING AT SIMMONS COLLEGE

Miss Helen Wood of Newton Highlands has been appointed as Director of the School of Nursing at Simmons College, according to an announcement made by President Bancroft Beatley. The appointment coincides with a reorganization of the school from a school of Public Health Nursing to one in which emphasis is placed on the undergraduate

preparation of nurses, to meet the changing demands in the professional nursing field

The present School of Public Health Nursing was organized in 1918, when there was a crying need for nurses prepared in this field. Through cooperation with the Massachusetts General Hospital, the Peter Bent Brigham Hospital and the Children's Hospital, students who completed the five year program received the degree of Bachelor of Science from the college, and a diploma from the school of nursing of the hospital where they received their technical training.

It is thought now, however, that many young women who wish to combine preparation for nursing with a liberal college education, according to the Simmons plan, may desire to enter other fields than that of Public Health Nursing. In order to give the best possible undergraduate preparation to young women who may wish to do administrative work in hospitals or become teachers of nursing, as well as to meet the demands of hospitals for young women adequately prepared in these fields, the new plan has been devised. Under it, students will continue to receive technical training from the hospitals, but this will be supplemented by increased liberal college preparation, both fields of study to be supervised by the college. Upon completion of the program which as formerly, will require five years of study Simmons will grant both the Bachelor of Science degree and the Diploma in Nursing. The hospitals with which the college is affiliated have shown interest in making whatever changes will give stronger professional preparation in nursing.

Work in Public Health Nursing will be continued but this field will be considered as a graduate field open to nurses who have already received their diplomas from other nursing schools, and to a selected number of senior students in accredited schools of nursing qualified to make a satisfactory affiliation with Simmons. The direction of all instruction in Public Health Nursing will be carried on by Miss Marjory Stimson, who has served as Acting Director of the School for the past two years.

The School of Nursing itself in its entire program especially the undergraduate work will be under the direction of Miss Wood who has been a special lecturer in Nursing Education at Simmons during the past year. A graduate of Mt Holyoke College and of the Massachusetts General Hospital School of Nursing, she received the degree of Master of Arts at Columbia University after completing special work in the field of Education. Most of her professional activities have been in the line of Nursing Education. She was Director of the School of Nursing at Washington University St. Louis from 1919-1923, and of the School of Nursing at the University of Rochester from 1924-1931. From 1926-1928 she was President of the New York State League of Nursing Education, and from 1931-1932

served as Acting Superintendent of Nurses at the Massachusetts General Hospital. She is a member of the National League for Nursing Education, and a representative of the American Nurses' Association on the National Committee on Grading Schools of Nursing.

LARGER AND BETTER MEDICAL MEETINGS

Certain trends in Medical Science have brought about modifications in the manner by which knowledge of medical matters is presented for discussion among doctors. In many respects these are all for the best. In certain respects, however, this is not true. Many of us remember a time when everyone knew nearly everyone else in medical Boston what he was doing and the value of his contributions.

Boston is bigger now and in our clinics many young men and women are working on research problems. It is not to be expected that there should be such a general diffusion of knowledge of what is going on and who is projecting it as was the case twenty five years ago. Another factor which enters the equation is the insistence of the College of Surgeons that every hospital desirous of maintaining a standardized ranking, shall hold hospital staff meetings. As a result of this the general and sectional meetings that used to attract doctors to a consideration of various topics of universal and special interest have less and less appeal and the complaint that there are too many medical meetings is very general, and is more often than any other offered as an excuse for nonattendance. When out-of-town speakers are persuaded to come to Boston to present papers they oftentimes attract a much smaller audience than their merit deserves, or than the medical prestige of the city should accord a visiting celebrity. There may come a time when the visitor's attitude will change and he may not feel it worth while to give of his best. So altogether the effect of too many small groups holding their own meetings tends to a disorganization of the local profession and a depreciation of its standards, which may foster a cliquishness that is disastrous to the morale of the profession.

Before any of these untoward results develop may it not be possible for all societies representing the medical interests of Greater Boston to come together in a unified endeavor to present a really worthwhile and representative series of meetings, covering the entire field of medicine planned for a year in advance and conducted under the auspices of the Boston Medical Library where many of the larger meetings are now held?

Such a plan need not interfere in any way with the routine meetings of these societies. It would only call for each one of them to put forth a special effort to present one particularly attractive program that would bring out an audience which would be truly representative of Boston's profession. It would

not be difficult to arrange such a program if enthusiastic coöperation could be secured and great benefit might result in many ways

Such a plan has been under discussion and is about to be undertaken. It is hoped that those who see this article will take the opportunity to give the matter some consideration, so that when they are approached, later on, to secure their coöperation they will feel inclined to lend their aid

A Committee Representing the Suffolk District Medical Society and the Boston Medical Library to Consider Coördination of Medical Society Meetings

GEORGE P. REYNOLDS, M.D.
CHARLES F. PAINTER, M.D.

MORTALITY RATES

Telegraphic returns from 86 cities, with a total population of thirty-seven millions for the week ending May 12, indicate a mortality rate of 11.9 as against a rate of 10.8 for the corresponding week of last year. The highest rate (18.6) appears for Wilmington, Del., and the lowest (5.1) for Waterbury, Conn. The highest infant mortality rate (19.3) appears for San Antonio, Texas, and the lowest for Albany, N. Y., Duluth, Minn., Erie, Pa., Evansville, Ind., Oklahoma City, Okla., Providence, R. I., and Spokane, Wash., which reported no infant mortality.

The annual rate for 86 cities is 12.5 for the nineteen weeks of 1934, as against a rate of 11.9 for the corresponding period of the previous year.

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS)
FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED
POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS
OF 1934 AND 1933

	Week ending		First 19 weeks	
	May 12, May 13,		1934	1933
	1934	1933		
Total deaths	151	150	2,976	2,624
Death rate	21.0	20.9	21.8	19.2
Deaths due to accidents in city	124	116	2,425	2,119
Death rate	17.3	16.2	17.8	15.5

PAYMENT OF DOCTORS WHO TREAT INDIGENT PATIENTS

Dr. S. S. Goldwater, Hospital Commissioner of New York City, advocated the payment of doctors who treat indigent patients in hospitals in an address before the Hospital Association of New York State, May 24, 1934.

He recommended this plan because of the serious economic conditions affecting doctors who are serving hospitals in which much time is devoted to caring for the poor.

HISTORICAL SKETCHES ON PUBLIC HEALTH PREPARED FOR THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH AND SPONSORED BY THE MASSACHUSETTS MEDICAL SOCIETY

EDWARD JENNER

BY ELEANOR J. MACDONALD, A.B.*

Old wives' tales and medical folk lore rarely pass the test of science. One by one they are discarded as knowledge advances. Occasionally, however, the ideas of simple country people regarding disease are forerunners of medical science. This was the case in regard to the tales told by dairy folk of Gloucestershire, England. They had observed that the milkmaids, who contracted a disease called cowpox from the cows, did not develop smallpox and the belief arose that individuals who had contracted the disease cowpox could never have smallpox. When we remember that most of those who had smallpox were left with a deeply pitted skin, we can well understand whence came the inspiration for the poets of those days to write about the beauty of the milkmaid, for she alone escaped smallpox and retained what we call to-day her schoolgirl complexion.

Two years before the Declaration of Independence was signed in Philadelphia a farmer in Yarmminster, England, Benjamin Jesty, voluntarily inoculated his wife and children with matter which he obtained from the cows with this disease. Later his children were inoculated with smallpox virus and did not contract the disease. This is the first recorded experiment of our present-day vaccination, but was disregarded until thirty years later.

It was Edward Jenner who furnished conclusive proof, which is accepted until this day that vaccination with cowpox protects against the disease smallpox. In 1762 when a lad of thirteen Jenner heard a young country woman say, speaking of smallpox, "I cannot take that disease for I have had the cowpox." This led Jenner to wonder if voluntary inoculation with cowpox would not be a preventive of the more serious disease. He was an apprentice to the famous surgeon, John Hunter, and had even helped in his experiments. He talked the matter over with Hunter and was advised, "Don't think, try, be patient, be accurate."

On May 14, 1796, he performed his first vaccination on a country boy, James Phipps, using the matter which he obtained from the arm of a milkmaid, Sarah Nelmes. This girl had contracted the disease from a cow. On July 1 Jenner inoculated Phipps with smallpox virus and the disease did not take. Within the next two years he had tried this experiment on twenty-three cases. He prepared a paper describing his work. The idea was taken up both in Europe and America and by the year 1800 about six thousand people had been vaccinated.

In Cambridge, Massachusetts, Dr. Benjamin Water

*Statistician, Division of Adult Hygiene, Massachusetts Department of Public Health.

house held the chair of the Hersey Professor of Theory and Practice at the Harvard Medical School. He is reported to have been the best educated physician in Massachusetts at that time, having studied in London, Edinburgh and Leyden. Dr Woodward says of him, "Dressing always in formal broad cloth and carrying a gold headed cane, somewhat condescending to his fellow practitioners whose knowledge he held in little esteem, contentious to a fault, with manners by no means agreeable, he was always in hot water and was eventually deprived of his professorship at the demand of all the other teachers in the school. A Jeffersonian Democrat when all his associates were Federalists, a member of the unpopular Society of Friends, a person almost universally disliked, this man of action overcoming all handicaps was nevertheless able—by hard work, persistence and the brilliancy of his intellect to place vaccination on a firm basis in this country for which work he was honored by scientific societies both here and abroad and by the London Medical Society voted the title of the American Jenner."

Dr Waterhouse, after hearing of Jenner's experiment obtained the material and on July 8, 1800, vaccinated his own son Daniel, aged five. He later vaccinated his three-year old son, a servant boy of twelve, and an infant of one. Other people asked for vaccination and he refused until he had proved that cowpox did protect against smallpox. To do this he wrote to Dr Aspinwall, a specialist of inoculation in New York.

"I have collected everything that has been printed respecting this distemper cowpox and have been so thoroughly convinced of its importance to humanity that I have procured some of the vaccine matter and therewith inoculated seven members of my family. My desire is to confirm the doctrine by having some of them inoculated by you. I can obtain varolious matter and inoculate them privately, but I wish to do it in the most open public way possible. As I have imported a new distemper I conceive the public have a right to know exactly every step I take in it. I write therefore to inquire whether you will on philanthropic principles try the experiment of inoculating some of my children who have undergone the cowpox. If you accede to my proposal I shall consider it an experiment in which we have coöperated for the good of our fellow citizens."

Waterhouse was so unduly disliked by other physicians that they were prejudiced against anything he advocated and it was nearly two years before he was able to persuade the Board of Health of Boston of the value of vaccination. That he did persuade them is evidenced by the announcement made by this Board.

The Board of Health for the town of Boston, are happy to have it in their power, this day to announce to their fellow-citizens the results of one of the most complete experiments which perhaps has ever been made, to prove the efficacy of the Cow

Pox, as a preventive against the Small Pox, and while they take the liberty to congratulate the public on this important discovery, they do earnestly recommend its introduction generally, and are confident that it will be the means of preserving the lives and adding to the happiness of millions."

In 1809 the State Legislature ordered every town, district and plantation where no Board of Health existed to choose three or more persons to supervise the inoculation of persons with cowpox. Between 1811 and 1837 there were but thirty nine deaths from smallpox in Boston, a far different story than in the two years 1697 and 1698 when one thousand individuals of a much less populous Boston had died.

CORRESPONDENCE

OVERHEARD, IN PASSING THE CARDIAC CLINIC—A DREAM

"Good morning, Mr Harty, how euphyllin?"

"Compensated, Cora mine, how are Theo, Min, ol right?"

"Yes there fine. Say, did you hear that Sy stole His' bundle?"

"No suffering cat units, digitol doc?"

"Well, I did, and he said, 'Nothing to it,' that Sy was the victim of a fib relation."

"Where's Traube?"

"Oh, hes second."

"Corrigan here?"

"No, hes always slow."

"Did I tell you about Ede Ma Mr Harty? Her legs, water sight! Squills and Southey tubes fixed her, and now she could do an Annette Kellerman!"

Swish—lub—dub—Here comes doc."

"Good morning, Cardiacs, Hitchensun! Before beginning the Clinic, we will join in the Cardiacs' hymn—Oh, let us have a thankful heart, from angry murmurs free."

"Righto, Nitro doc!" (They sing)

WM PEARCE COUES, M D

not be difficult to arrange such a program if enthusiastic coöperation could be secured and great benefit might result in many ways

Such a plan has been under discussion and is about to be undertaken. It is hoped that those who see this article will take the opportunity to give the matter some consideration, so that when they are approached, later on, to secure their coöperation they will feel inclined to lend their aid.

A Committee Representing the Suffolk District Medical Society and the Boston Medical Library to Consider Coördination of Medical Society Meetings

GEORGE P. REYNOLDS, M.D.
CHARLES F. PAINTER, M.D.

MORTALITY RATES

Telegraphic returns from 86 cities, with a total population of thirty-seven millions for the week ending May 12, indicate a mortality rate of 11.9 as against a rate of 10.8 for the corresponding week of last year. The highest rate (18.6) appears for Wilmington, Del., and the lowest (5.1) for Waterbury, Conn. The highest infant mortality rate (19.3) appears for San Antonio, Texas, and the lowest for Albany, N. Y., Duluth, Minn., Erie, Pa., Evansville, Ind., Oklahoma City, Okla., Providence, R. I., and Spokane, Wash., which reported no infant mortality.

The annual rate for 86 cities is 12.5 for the nineteen weeks of 1934, as against a rate of 11.9 for the corresponding period of the previous year.

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS)
FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED
POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS
OF 1934 AND 1933

	Week ending		First 19 weeks	
	May 12, May 13,		1934	1933
	1934	1933		
Total deaths	151	150	2,976	2,624
Death rate	21.0	20.9	21.8	19.2
Deaths due to ac-				
cidents in city	124	116	2,425	2,119
Death rate	17.3	16.2	17.8	15.5

PAYMENT OF DOCTORS WHO TREAT INDIGENT PATIENTS

Dr. S. S. Goldwater, Hospital Commissioner of New York City, advocated the payment of doctors who treat indigent patients in hospitals, in an address before the Hospital Association of New York State, May 24, 1934.

He recommended this plan because of the serious economic conditions affecting doctors who are serving hospitals in which much time is devoted to caring for the poor.

HISTORICAL SKETCHES ON PUBLIC HEALTH PREPARED FOR THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH AND SPONSORED BY THE MASSACHUSETTS MEDICAL SOCIETY

EDWARD JENNER

BY ELEANOR J. MACDONALD, A.B.*

Old wives' tales and medical folk lore rarely pass the test of science. One by one they are discarded as knowledge advances. Occasionally, however, the ideas of simple country people regarding disease are forerunners of medical science. This was the case in regard to the tales told by dairy folk of Gloucestershire, England. They had observed that the milkmaids, who contracted a disease called cowpox from the cows, did not develop smallpox and the belief arose that individuals who had contracted the disease cowpox could never have smallpox. When we remember that most of those who had smallpox were left with a deeply pitted skin, we can well understand whence came the inspiration for the poets of those days to write about the beauty of the milkmaid, for she alone escaped smallpox and retained what we call to-day her schoolgirl complexion.

Two years before the Declaration of Independence was signed in Philadelphia a farmer in Yarmouth, England, Benjamin Jesty, voluntarily inoculated his wife and children with matter which he obtained from the cows with this disease. Later his children were inoculated with smallpox virus and did not contract the disease. This is the first recorded experiment of our present-day vaccination, but was disregarded until thirty years later.

It was Edward Jenner who furnished conclusive proof, which is accepted until this day, that vaccination with cowpox protects against the disease smallpox. In 1762 when a lad of thirteen, Jenner heard a young country woman say, speaking of smallpox, 'I cannot take that disease for I have had the cowpox.' This led Jenner to wonder if voluntary inoculation with cowpox would not be a preventive of the more serious disease. He was an apprentice to the famous surgeon, John Hunter, and had even helped in his experiments. He talked the matter over with Hunter and was advised, 'Don't think, try, be patient, be accurate.'

On May 14, 1796, he performed his first vaccination on a country boy, James Phipps, using the matter which he obtained from the arm of a milkmaid Sarah Nelmes. This girl had contracted the disease from a cow. On July 1 Jenner inoculated Phipps with smallpox virus and the disease did not take. Within the next two years he had tried this experiment on twenty-three cases. He prepared a paper describing his work. The idea was taken up both in Europe and America and by the year 1800 about six thousand people had been vaccinated.

In Cambridge, Massachusetts, Dr. Benjamin Water

*Statistician, Division of Adult Hygiene, Massachusetts Department of Public Health.

house held the chair of the Hersey Professor of Theory and Practice at the Harvard Medical School. He is reported to have been the best educated physician in Massachusetts at that time, having studied in London, Edinburgh and Leyden. Dr Woodward says of him, "Dressing always in formal broad cloth and carrying a gold headed cane, somewhat condescending to his fellow practitioners whose knowledge he held in little esteem contentions to a fault, with manners by no means agreeable, he was always in hot water and was eventually deprived of his professorship at the demand of all the other teachers in the school. A Jeffersonian Democrat when all his associates were Federalists a member of the unpopular Society of Friends a person almost universally disliked, this man of action overcoming all handicaps was nevertheless able—by hard work persistence and the brilliancy of his intellect to place vaccination on a firm basis in this country for which work he was honored by scientific societies both here and abroad and by the London Medical Society voted the title of the American Jenner.

Dr Waterhouse, after hearing of Jenner's experiment, obtained the material and on July 8, 1800 vaccinated his own son Daniel aged five. He later vaccinated his three-year-old son, a servant boy of twelve, and an infant of one. Other people asked for vaccination and he refused until he had proved that cowpox did protect against smallpox. To do this he wrote to Dr Aspinwall, a specialist of inoculation in New York.

I have collected everything that has been printed respecting this distemper cowpox and have been so thoroughly convinced of its importance to humanity that I have procured some of the vaccine matter and therewith inoculated seven members of my family. My desire is to confirm the doctrine by having some of them inoculated by you. I can obtain variolous matter and inoculate them privately, but I wish to do it in the most open public way possible. As I have imported a new distemper I conceive the public have a right to know exactly every step I take in it. I write therefore to inquire whether you will on philanthropic principles try the experiment of inoculating some of my children who have undergone the cowpox. If you accede to my proposal I shall consider it an experiment in which we have coöperated for the good of our fellow citizens.

Waterhouse was so unduly disliked by other physicians that they were prejudiced against anything he advocated and it was nearly two years before he was able to persuade the Board of Health of Boston of the value of vaccination. That he did persuade them is evidenced by the announcement made by this Board.

The Board of Health for the town of Boston are happy to have it in their power, this day, to announce to their fellow citizens the results of one of the most complete experiments which perhaps has ever been made to prove the efficacy of the Cow

Pox, as a preventive against the Small Pox, and while they take the liberty to congratulate the public on this important discovery, they do earnestly recommend its introduction generally, and are confident that it will be the means of preserving the lives and adding to the happiness of millions."

In 1809 the State Legislature ordered every town, district and plantation where no Board of Health existed to choose three or more persons to supervise the inoculation of persons with cowpox. Between 1811 and 1837 there were but thirty nine deaths from smallpox in Boston, a far different story than in the two years 1697 and 1698 when one thousand individuals of a much less populous Boston had died.

NOTICE

1934 GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Seventh Annual Graduate Fortnight of The New York Academy of Medicine will be devoted to a consideration of Gastrointestinal Diseases. The Fortnight will be held October 22 to November 2.

Sixteen important hospitals of the city will present coordinated afternoon clinics and clinical demonstrations. At the evening meetings prominent clinicians from various parts of the country who are recognized authorities in their special lines of work will discuss the various aspects of the general subject.

A comprehensive exhibit of anatomical, bacteriological and pathological specimens and research material will be shown. Many of the exhibits will be demonstrated.

Among the subjects to be presented at the evening meetings and in the hospital programs will be General principles involved in the diagnosis of gastro-intestinal diseases—Medical, Surgical, Roentgenological.

Constipation

Diarrhea

Physiology of the gastrointestinal tract

Diseases of the pancreas, especially acute pancreatitis and its treatment

Diseases of the esophagus

Functional diseases of the stomach

Disorders of the gastrointestinal tract in children—Infections, Management, Surgery in infants and children

Diet in relation to gastrointestinal diseases in infancy

Clinical examination of the patient from the surgeon's and the internist's points of view

Demonstrations of diets used in treatment

Peptic ulcer—Medical discussion, Surgical discussion

Carcinoma of the stomach

Chronic lesions in the paracecal region

Acute appendicitis

Peritonitis

Gall bladder and biliary passages—Medical discussion, Surgical discussion

Jaundice

Tumors of the colon

Diseases of the rectum including tumors

Intestinal obstruction

Diverticulitis

Colitis, amebiasis, functional disturbances of the colon including mucous colitis

Hirschsprung's Disease

Lymphogranulomata

Clinical methods and differential diagnosis

Technique of the gastro-intestinal series

Laboratory examinations

The profession generally is invited to attend.

A complete program and registration blank may be

secured by addressing—Dr. Frederick P. Reynolds, The New York Academy of Medicine, 2 East 103d Street, New York City.

REPORT AND NOTICE OF MEETINGS

ELECTION OF DELEGATES TO THE NEW ENGLAND MEDICAL COUNCIL

At the Annual Meeting of the Connecticut State Medical Society, Dr. Walter R. Steiner, President, Dr. Charles W. Comfort, Jr., Secretary, Dr. George Blumer, Dr. Daniel Sullivan and Dr. Thomas P. Murdock were elected delegates to the New England Medical Council.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The thirteenth annual scientific and clinical session of the American Congress of Physical Therapy will be held in Philadelphia at the Bellevue Stratford, September 10, 11, 12, 13, 1934.

On Wednesday evening, September 12, a joint session will be held with the Philadelphia County Medical Society.

Special features will be the scientific and technical exhibits and the small group conferences. The latter have been arranged for Tuesday morning. Every specialty of medicine and surgery will be represented. The technical application of physical measures will be demonstrated. The general sessions will be taken up with symposia on cancer, arthritis, poliomyelitis, industrial surgery, etc.

Friday, September 14, has been set aside for hospital teaching clinics which will be held in the leading institutions of Philadelphia.

Send for preliminary program. Address: American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Illinois.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

June 7—Faulkner Hospital Clinical Meeting will be held at 5 P.M.

June 7, 8, 9—Annual Meeting of the American Association for the Study of Gout will be held in Cleveland, Ohio. For details of the program apply to Dr. J. R. Yung, Terre Haute, Ind.

June 11—American Medical Golfing Association will meet at the Mayfield Country Club in Cleveland. For details see page 1090, Issue of May 17.

June 11-12—The American Proctologic Society will meet at the Hotel Cleveland, Cleveland. For information address the Secretary, Frank G. Runyon, M.D., 1361 Perkiomen Avenue, Reading, Pa.

June 12—South End Medical Club will meet at the office of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, at 12 noon.

June 12—Boston Society of Anesthetists will meet at the Hotel Kenmore, Boston. For details write Dr. Philip D. Woodbridge, 605 Commonwealth Avenue, Boston.

June 12—American Heart Association will meet at 9:30 A.M. at the Cleveland Hotel, Cleveland, Ohio.

July 24-31—The IVth International Congress of Radiology will be held in Zurich under the presidency of Professor H. R. Schenk. General Secretary Dr. H. E. Walther, Gloriastrasse 14, Zurich.

August 18-September 30—Medical Study Trip to Hungary. See page 975, Issue of May 10.

September 3 6—American Public Health Association at Pasadena, California Dr J D Dunshee, Chairman, Local Committee on Arrangements

September 4, 5, 6—International Union Against Tuberculosis. For information address the National Tuberculosis Association, 450 Seventh Avenue New York City

September 10, 11, 12, and 13—American Congress on Physical Therapy See page 1240

October 22 - November 2—1934 Graduate Fortnight of the New York Academy of Medicine See page 1240

October 31 November 2—Massachusetts State Nurses Association, Hotel Statler Boston. For information write Miss Helene G Lee R N 420 Boylston Street, Boston

BOOK REVIEWS

Medicine A Voyage of Discovery By Josef Löbel
334 pp New York Farrar & Rinehart, Inc \$3 00

This volume is a popular account of medicine from the point of view of one who not only has a wide knowledge of the subject but is also trained in philosophy. The author is not known in this country. He writes in a pleasant style and the book is distinctly superior to certain other books of a similar character which have been published in recent years. There are however a number of gross mistakes in historical facts, the typography leaves a good deal to be desired, and the appearance of the book is somewhat marred by the use of the symbol of Mercury in place of the caduceus. Of local interest is a detailed account by a Berlin surgeon of an operation by Dr Harvey Cushing at the Peter Bent Brigham Hospital, a few years ago.

Although this book can be highly recommended for its broad base and sound philosophy with its pleasant sense of humor, one wishes that the author had been a little more careful in his historical references and that the volume had been placed with a publisher who had a more adequate sense of producing a fitting book free from minor errors.

The Elements of Experimental Embryology By Julian S Huxley and G R De Beer 514 pp
Cambridge The University Press \$7 00

This book correlates a great amount of factual material concerning embryological development in various species. Systematizing as it explains it unfolds a beautiful pattern of meticulous organization as the reader progresses through its pages. It does for embryology what the philosopher performs with the facts of science rescuing principles from a great mass of seemingly disorganized and unrelated experiments. This is attested by the bibliography of 36 pages which appears at the end of the book.

Proof for the deductions made by the authors is derived wholly from biological experiments. Where as the work includes implications of the physiological it does not answer the why and wherefore of the phenomena described in terms of specific biochemical reactions. It therefore builds a framework, the substance for the clothing of which must still be supplied.

Tissues in the early embryo tend to differentiate according to their position in response to local in-

fluences called "organisers" or groups of directing cells. In this way mosaic fields are established throughout the embryo each of which has a dominant influence in its own region and a modifying influence upon its neighbors. Because mosaic fields are not precise morphological units but overlap one another (gradient fields) a wide variation in response may occur by changes in external and internal forces. Very young tissues are especially susceptible to changes in environment, but as the mosaic field becomes more firmly established the range of reaction lessens.

The book is written in a clear style and contains many well chosen illustrations.

An Outline of Immunity By W W C Topley 415 pp
Baltimore William Wood and Company \$6 00

This book is an excellent presentation of scientific medicine. The value of its contents lies in the various fields of immunology, tissue resistance, treatment of disease, prevention of disease presented intelligently. There is not any rationalization empiricism or individualism between its covers. It is a pleasure to study the book's contents.

Anyone in the practice of medicine or surgery, fourth year medical students and internes can learn from this book.

It is so sound and clear, well presented and complete that it stimulates one to combine its principles with the daily practice of medicine and surgery.

The chapters entitled "The Application of Immunity in Treatment" and "The Application of Immunity in Diagnosis" are of great value and practical.

This book can stand on its own merits.

Treatment of the Commoner Diseases By Lewellys F Barker 317 pp
Philadelphia J B Lippincott Company \$3 00

This book is based on a series of postgraduate lectures designed to bring to the general practitioner the modern methods of treatment of common ailments. One has learned to look forward to the usually brilliant writings of Dr Barker with keen anticipation, but this book is a distinct disappointment.

Despite his qualifying statement in his preface that "I shall make no attempt to discuss fully and completely any topic whatever" it appears to the reviewer that in the face of mounting medical publications a new book requires more justification than merely the fact that it is an outgrowth of a series of lectures. The result is an extremely fragmentary work which in the long run defeats its purpose. Throughout the book there is a tendency to use a complex terminology.

There are frequent allusions to proprietary preparations using the trade name where a pharmacopoeial product may be used and which in some cases have actually been rejected by the A M A as being

of secret composition or unacceptable for other reasons. The book is burdened with many statements of dubious acceptability or partial or complete inaccuracy. Thus he alludes (p 22) to the great increase in the large mononuclears in acute infectious mononucleosis without reference to the usually accepted fact that the lymphocytes are predominantly increased and any increase in monocytes is a concomitant feature.

For foreign protein shock therapy we are aware, of course, of the use of dead typhoid bacilli. The author recommends a dose "beginning with, say, 500,000,000 dead bacilli in $\frac{1}{2}$ cc of fluid, repeating the same dose in one week and at the end of the second week giving double this dose" (P 28). This strikingly resembles the routine practiced in typhoid immunization in which instance the organisms are injected subcutaneously or intramuscularly and the reactions are chiefly local. Any systemic reactions usually prove to be mild and unimportant. The primary intention in pursuing shock therapy is the creation of the reaction recognized as due to the foreign protein when intravenously injected. The route of injection is not specified. The dose recommended is at least ten times the usual initial dose and the augmentation of the subsequent doses is out of proportion. He also advocates the use of fresh sterilized milk without mentioning the need for removing the fat from the milk.

Cardiologists are skeptical regarding the efficacy of camphor in oil as a vasomotor stimulant. Strophanthin is advised far too frequently without sufficient stress on the potential dangers. The reviewer believes that the myth regarding nutrient enemata (other than salt solution) seems pretty well exploded. Discussing the treatment of pneumonia not many clinicians will subscribe to the following: "For the support of the heart, it is a good rule to begin the administration of small doses of digitalis on the very first day of the disease. In patients who have good hearts to begin with, $\frac{3}{4}$ grain of powdered digitalis leaf in pill form twice a day will suffice, though if the pneumonia occurs in a patient whose heart was diseased before the attack, it is wise to begin with a grain and a half of powdered leaf administered from three to five times in the 24 hours for the first two days. In addition to digitalis, 20% camphorated oil (5 or 10 cc.) should be injected into the gluteal muscle twice a day."

The statement that, "according to the type of pneumococcus found to be the cause of the pneumonia we inject a corresponding immune serum (type I, type II, or type III), giving 100 cc every eight hours" certainly warrants correction in that there is no immune serum for type III and since the use of the concentrated sera the dose of 100 cc is unnecessary.

The use of 1 to 3 grains of phenylhydrazine once a week in the treatment of polycythemia is essen-

tially meaningless. If there is any disease where individualization and correlation of treatment to blood counts is essential, it is this disease. Is there any value to "15-20 drops of 1:1000 solution of adrenalin given by mouth 3 times a day" (p 143) in bleeding gastric ulcer? In the treatment of hemorrhoids mention of the use of mineral oil is entirely omitted. Paravertebral anesthesia for gallstone pain is hardly a procedure to recommend to general practitioners, as a matter of fact such practice must be excessively rare.

Individually estimated many of the issues raised are of minor importance but in the aggregate they tend to vitiate the value of the book and it seems incredible that it has come from the pen of this master.

Contagious Diseases What They Are and How to Deal with Them By W W Bauer First Edition
218 pp New York Alfred A. Knopf. \$2.00

This very readable book of two hundred pages gives the lay reader the facts which he or she should know, and at times may badly want to know, about the communicable diseases. Both in common sense and in scientific data it is as accurate as our present knowledge of its subject matter permits, the style is easy and frequently humorous, yet obviously the information imparted is authoritative.

The first chapter is a primer of bacteriology, from this introduction the book proceeds to a discussion of quarantine regulations and the home care of those sick with communicable disease, descriptions of these diseases and the obvious duty of prevention, both by specific immunizations, where those are possible, and by the avoidance of contacts. The question of immunization is temperately dealt with, the author has allowed no unwarranted enthusiasms to warp his judgment or prejudice the considered results of his experience. Intended for the lay individual, this book contains information which the busy practitioner himself may find of value in his daily rounds.

Brucella Infections in Animals and Man Methods of laboratory diagnosis By I. Forest Huddleson
108 pp New York The Commonwealth Fund

The increased recognition of undulant fever in man and the great economic importance of contagious abortion in animals is ample justification for the publication of this monograph, which deals essentially with the methods of laboratory diagnosis of the infection. The work is largely concerned with methods of serological diagnosis although some attention is paid to the pathology of the conditions and the bacteriological features of the group. Several excellent illustrations add to the value of the paper, as does a well-chosen bibliography. For those pathologists and bacteriologists coming in contact with Brucella infections, this monograph will prove exceedingly valuable.

THE IMPORTANCE OF DISTURBANCES IN NUTRITION IN EDEMATOUS STATES*

BY WARFIELD T. LONGCOPE, M.D.†

ONE of the most notable contributions that has been made to medicine during the last quarter of a century is the discovery of the accessory food factors the vitamins. With a comprehension of the significance of the vitamins has come an increasing interest in the subject of malnutrition in its broadest sense. As a result of innumerable investigations the tendency has grown within recent years to gather into one group a number of disease states that have been defined somewhat loosely as the deficiency diseases. The deficiency which is common to all of them is an inadequate amount of some substance in the food which is necessary to the body for its proper nutrition, or the inability of the body to absorb, or to prepare for absorption, these necessary substances even though the diet contains sufficient quantities of them.

The disturbances in nutrition that result from these defective diets or from the inability to utilize the constituents of a completely adequate diet are numerous and very varied. It is not necessary to dwell upon those well-defined diseases, such as scurvy, which are caused by the lack of specific vitamins, or to emphasize in this gathering the brilliant work of Minot and Murphy and of Castle on pernicious anemia. It would not be amiss, however, to recall the fact that it is not ordinarily an inadequate diet that causes pernicious anemia but the inability of the stomach to form the necessary factor, present in normal liver, that is essential to the proper formation of red cells.

Although pernicious anemia, pellagra, sprue, possibly the idiopathic steatorrhea or celiac disease, and even hunger edema possess individual characteristics that give them the distinction of clinical and etiological entities, there are considerable numbers of patients who suffer from profound disturbances of nutrition in which the clinical picture is not so clear cut, and in which, in addition to malnutrition, several features peculiar to two or more of the above diseases may be combined in a most confusing manner. The variations in symptoms and signs may be numerous. There may be great loss of weight, anemia

either of the microcytic or macrocytic type, persistent diarrhea, glossitis, steatorrhea, skin eruptions, abnormalities in mineral metabolism and alterations in the exchange of fluids, so that in some patients there is dehydration of the subcutaneous tissues while in others such extensive edema that it becomes one of the predominant features of the illness.

The complexity of the situation, as we have observed it in several patients during the last few years, the comparative frequency of edema in mild states of malnutrition, and the presence of edema in some forms of dietary deficiency under unexpected circumstances have led us to pay some attention to these conditions.

Since a large part of our work as physicians must unfortunately be devoted to the repair of function rather than to the restitution of damaged organs, it is desirable to analyze in some detail the cause of symptoms in the hope that we may find some way of eliminating them or of shedding more light on the entire disease process. It is with this idea in mind that I would like to discuss the question of nutritional edema and to describe the observations that we have made in a few patients suffering from this condition. In none of these patients was there disease of the heart or kidneys, so that for the moment we are not concerned with either cardiac or nephritic edema.

It is not my intention, and it is quite beyond my province, to discuss the complicated problem of edema in general. It is necessary, however, to state briefly some of the views that are now generally held concerning the different factors that may, in one way or another, be held responsible for the formation of subcutaneous edema or effusions into the serous cavities.

According to most authorities it is supposed that at least four factors may be concerned with the accumulation of abnormal amounts of fluid in the connective tissue spaces or serous cavities or, in other words, with the production of edema. The first of these is the state of permeability of the capillary or vessel wall. Injury of the vessel wall allows fluid to escape into the surrounding tissues. Inflammatory edema and angioneurotic edema arise in this manner. The second is concerned with the quantitative and qual-

*The Shattuck Lecture delivered at the Annual Meeting of the Massachusetts Medical Society, Worcester, June 4, 1934.
†Longcope, Warfield T.—Professor of Medicine, Johns Hopkins Medical School. For record and address of author see "This Week's Issue," page 1297.

itative relationships between the electrolytes in the blood and tissue spaces, the third is the elevation of hydrostatic pressure within the capillaries or small blood vessels, which is of particular importance in the formation of edema in congestive heart failure, and the fourth is the amount of colloid osmotic pressure exerted by the plasma proteins. The last three of these forces act in relation to somewhat equivalent conditions in the tissue spaces, and it is largely a disturbance in the equilibrium normally maintained between the intravascular and extravascular forces that leads to a reversal of the normal exchange of fluids and electrolytes, and that determines the accumulation of fluid, as dropsy, in the tissue spaces or serous sacs.

Before considering the matter in its clinical aspect it is necessary to dwell for a moment on one theory of the formation of edema to which I shall have frequent occasion to refer. This is the importance of the relation of the colloid osmotic pressure of the proteins of the blood plasma to the formation of edema. Starling¹ first propounded the theory that the filtration of fluid from the blood vessels to the tissue spaces depended upon the balance between the hydrostatic pressure within the blood vessels and the colloid osmotic pressure of the plasma, the former tending to force fluid from the blood vessels into the tissues, the latter tending to hold fluids within the blood vessels. The theory has been developed experimentally by Govaerts² and again recently by Landis³, and it has been supported by the work of Leiter⁴ and of Barker and Kirk⁵, it upholds Epstein⁶ in his conception of the origin of nephrotic edema and it is dealt with fully by Van Slyke and Peters⁷ and by many investigators who have recently devoted considerable attention to this phase of the problem.

From the extensive investigations that have been made on this subject it is generally assumed, according to the work of Moore and Van Slyke that when the total plasma proteins fall from their normal level of 60 to 80 grams per cent to 55 grams per cent, edema is likely to develop. This is due to the resulting decrease in colloid osmotic pressure of the plasma. The most important protein, in this respect however, is the albumen, for it not only forms about 60 per cent of the plasma protein but is estimated to have a colloid osmotic pressure, according to Govaerts² of 55 mm. of Hg per gram, whereas globulin forming only about 40 per cent has a colloid osmotic pressure of only 14 mm. of Hg per gram. Thus decrease of the plasma albumen is much more effective than decrease of plasma globulin in leading to a reduction in the colloid osmotic pressure of the plasma.

Therefore it is conceivable that any abnormality which leads to a continuous loss of albumen from the body may result, sooner or later, in a serious depletion of serum albumen

and consequently predispose to the formation of dropsy. A familiar example is the edematous form of Bright's disease in which large amounts of serum albumen are lost daily in the urine. There are other ways, however, in which the body may lose large amounts of protein, for this may occur after repeated hemorrhages, from draining wounds, through empyema sinuses, from chronic inflammations of the bowel, and from diseases of the gastro-intestinal tract that interfere with the normal absorption of protein. Though these may be of secondary importance, they must occasionally be taken into consideration.

Undoubtedly the most important and the commonest method of depriving the body of protein, however, is through a prolonged or excessive reduction of protein in the diet. Though it has only recently been discovered, as I shall point out, that there is a close connection between protein starvation and the formation of edema, the occurrence of dropsy in states of advanced undernutrition has attracted attention for centuries⁸. It has been described as occurring in epidemics, and for this reason has been called "epidemic dropsy". The descriptive terms used in the literature serve in themselves to indicate the conditions under which it was likely to occur, for we find it referred to as "war edema", "prison dropsy", "hunger swelling" and "deficiency edema". There are interesting accounts of the dropsy which was widespread in the French Army during the Wars of the Sixteenth Century and which was common in the armies of Napoleon. The interesting observation was also made that the swelling was much greater in the soldiers on march or on duty than in those too sick to move about. Many children confined in Paris during the Siege of 1870-71 became edematous, and in the great famines of India and Russia the people have been described as "swollen with hunger".

Edema of both children and adults was very common in the central countries of Europe during the war and received an exhaustive study by Schittenhelm and Schlecht⁹. They observed that the edema was marked when the patients were up and about, but that it was likely to disappear when they were put to bed, and they pointed out that the diet was largely fluid, grossly deficient in protein and very rich in salt. Shortly after the war Maver⁸, after making a survey of these types of edema, came to the conclusion that the disease did not seem to be a deficiency disease, in the sense that the diet was deficient in one or more specific unknown constituents, such as the vitamins, but in a broader sense it was a deficiency disease since the diet was very low in total calories and was lacking particularly in protein. Denton and Kohman¹⁰ had already shown that a large proportion of rats fed on a diet of carrots developed edema when nitrogen in the diet was reduced, and the necessary calories substituted by

the addition of some non-nitrogenous food stuffs such as carbohydrate and fat, while at about the same time Kohman¹¹ had been able to prevent the edema occurring in rats which were fed on carrots but supplied with adequate amounts of vitamins by adding a sufficient quantity of protein to the ration without changing the caloric value. Frisch, Mendel and Peters¹² were finally able to demonstrate that the one necessary component of the food which would prevent rats from showing edema during similar feeding experiments was protein. They also found that restriction of the protein of the food of the rats was accompanied by a reduction in the proteins of the plasma, and that there was a close correlation between the degree of the reduction of plasma proteins and the occurrence of edema.

These experiments have opened a way for the study of many types of edema in which the depletion of plasma proteins may come from the privation of protein rather than from the loss of protein from the body. Though the total plasma proteins and their fractions have been determined in a great number of diseases¹³, it is to Peters¹⁴ and his collaborators that we are particularly indebted for demonstrating the frequency with which low plasma proteins and especially low values for plasma albumen are associated on the one hand with malnutrition and, on the other, with edema. They have shown that the three conditions, malnutrition, hypoproteinemia and edema may be related in diseases as varied as diabetes mellitus, neoplasms, infections of various sorts, anemia and disease of the liver.

Nutritional diseases of all sorts are prevalent in China, and the frequent occurrence of edema in these patients induced Weech and Ling¹⁵ to investigate the relationship between the occurrence of dropsy and the level of plasma proteins in eighteen patients. The diets of these patients were deficient in all respects, but particularly in the protein food stuffs of animal origin. They found a fairly close correlation between the level of total plasma proteins and the development of edema, but the relationship was most definite between the albumen deficit and the dropsy. They state that edema was never absent, except in one case, when the serum albumen was less than 2.5 grams per 100 cc and was never present when, during convalescence, the serum albumen was greater than 2.9 grams per 100 cc of plasma, the normal range in their experiments being 3.6 grams to 5.0 grams of serum albumen per 100 cc of plasma. Youmans¹⁶ and his collaborators have estimated the plasma proteins in thirty-one patients who suffered with mild edema supposedly due to chronic malnutrition. In the majority of these patients the total plasma proteins were normal, but in many the plasma albumen was slightly, though not remarkably, reduced below the nor-

mal. It was only in an occasional instance that the total plasma proteins, the plasma albumen or the colloid osmotic pressure was lowered to what is generally regarded as the critical level for the appearance of edema. Youmans raises the question, on this account, as to whether there might be additional factors in these patients that contribute to the formation of edema.

Though lack of protein in the food and subsequent hypoproteinemia seem to form the basis for the production of nutritional edemas, it is undoubtedly necessary to consider whether there may not be accessory factors that must be taken into account, for discrepancies are observed and profound nutritional disturbances may be seen without edema, and edema may be present with relatively high plasma proteins^{16, 17}.

It has repeatedly been observed that when poorly nourished people or animals drink large quantities of water the edema increases^{6, 9, 10, 11, 12}, and it has been pointed out that this is one of the essential features in the formation of war dropsy and famine edema. Perhaps of even more importance is the relation which the use of sodium chloride and sodium bicarbonate bears to the formation of these edemas¹⁸, for it has been shown^{15, 17} that the administration of sodium chloride and sodium bicarbonate to patients with nutritional edema leads to a rapid increase in the dropsy and that the administration of sodium chloride or sodium bicarbonate to dogs with experimentally induced hypoproteinemia precipitates or exaggerates the edema^{19, 20}. It seems probable too, both from the repeated observations made upon the war and famine edemas and from more exact studies recently reported²¹ that the erect position exaggerates the edema when it is present, or may be the determining factor in causing the appearance of dropsy when the edema is, so to speak, latent. Mild degrees of heart failure may also exert an important influence in exaggerating or precipitating edema, and since the symptoms of myocardial failure are common in severe anemia, this factor must also be taken into account in some instances of nutritional dropsy. The post-operative nutritional edema in which at times the dropsy may reach serious proportions, prevents a most complicated problem. The recent studies of Jones, Eaton and White²⁴ indicate how many accessory factors must be taken into consideration. Nitrogen starvation is of prime importance, but the administration of excessive amounts of water and of sodium chloride, the drainage of serous material or the presence of infections may be the determining factor in the actual appearance of edema, may exaggerate it, or serve to prolong the dropsy.

The occurrence of edema associated with improper digestion or absorption of protein has received much less attention than the starvation edemas. Yet edema of nervous system

itative relationships between the electrolytes in the blood and tissue spaces, the third is the elevation of hydrostatic pressure within the capillaries or small blood vessels, which is of particular importance in the formation of edema in congestive heart failure, and the fourth is the amount of colloid osmotic pressure exerted by the plasma proteins. The last three of these forces act in relation to somewhat equivalent conditions in the tissue spaces, and it is largely a disturbance in the equilibrium normally maintained between the intravascular and extravascular forces that leads to a reversal of the normal exchange of fluids and electrolytes, and that determines the accumulation of fluid, as dropsy, in the tissue spaces or serous sacs.

Before considering the matter in its clinical aspect it is necessary to dwell for a moment on one theory of the formation of edema to which I shall have frequent occasion to refer. This is the importance of the relation of the colloid osmotic pressure of the proteins of the blood plasma to the formation of edema. Starling¹ first propounded the theory that the filtration of fluid from the blood vessels to the tissue spaces depended upon the balance between the hydrostatic pressure within the blood vessels and the colloid osmotic pressure of the plasma, the former tending to force fluid from the blood vessels into the tissues, the latter tending to hold fluids within the blood vessels. The theory has been developed experimentally by Govaerts² and again recently by Landis³, and it has been supported by the work of Leiter⁴ and of Barker and Kirk⁵, it upholds Epstein⁶ in his conception of the origin of nephrotic edema and it is dealt with fully by Van Slyke and Peters⁷ and by many investigators who have recently devoted considerable attention to this phase of the problem.

From the extensive investigations that have been made on this subject it is generally assumed, according to the work of Moore and Van Slyke that when the total plasma proteins fall from their normal level of 60 to 80 grams per cent to 55 grams per cent, edema is likely to develop. This is due to the resulting decrease in colloid osmotic pressure of the plasma. The most important protein, in this respect however, is the albumen, for it not only forms about 60 per cent of the plasma protein, but is estimated to have a colloid osmotic pressure, according to Govaerts² of 55 mm. of Hg per gram, whereas globulin forming only about 40 per cent has a colloid osmotic pressure of only 14 mm. of Hg per gram. Thus decrease of the plasma albumen is much more effective than decrease of plasma globulin in leading to a reduction in the colloid osmotic pressure of the plasma.

Therefore it is conceivable that any abnormality which leads to a continuous loss of albumen from the body may result, sooner or later, in a serious depletion of serum albumen

and consequently predispose to the formation of dropsy. A familiar example is the edematous form of Bright's disease in which large amounts of serum albumen are lost daily in the urine. There are other ways, however, in which the body may lose large amounts of protein, for this may occur after repeated hemorrhages, from draining wounds, through empyema sinuses, from chronic inflammations of the bowel, and from diseases of the gastro-intestinal tract that interfere with the normal absorption of protein. Though these may be of secondary importance, they must occasionally be taken into consideration.

Undoubtedly the most important and the commonest method of depriving the body of protein, however, is through a prolonged or excessive reduction of protein in the diet. Though it has only recently been discovered, as I shall point out, that there is a close connection between protein starvation and the formation of edema, the occurrence of dropsy in states of advanced undernutrition has attracted attention for centuries⁸. It has been described as occurring in epidemics, and for this reason has been called "epidemic dropsy". The descriptive terms used in the literature serve in themselves to indicate the conditions under which it was likely to occur, for we find it referred to as "war edema", "prison dropsy", "hunger swelling" and "deficiency edema". There are interesting accounts of the dropsy which was widespread in the French Army during the Wars of the Sixteenth Century and which was common in the armies of Napoleon. The interesting observation was also made that the swelling was much greater in the soldiers on march or on duty than in those too sick to move about. Many children confined in Paris during the Siege of 1870-71 became edematous, and in the great famines of India and Russia the people have been described as "swollen with hunger".

Edema of both children and adults was very common in the central countries of Europe during the war and received an exhaustive study by Schittenhelm and Schlecht⁹. They observed that the edema was marked when the patients were up and about, but that it was likely to disappear when they were put to bed, and they pointed out that the diet was largely fluid, grossly deficient in protein and very rich in salt. Shortly after the war Mayer³, after making a survey of these types of edema, came to the conclusion that the disease did not seem to be a deficiency disease, in the sense that the diet was deficient in one or more specific unknown constituents, such as the vitamins, but in a broader sense it was a deficiency disease since the diet was very low in total calories and was lacking particularly in protein. Denton and Kohman¹⁰ had already shown that a large proportion of rats fed on a diet of carrots developed edema when nitrogen in the diet was reduced, and the necessary calories substituted by

heart was normal in size, there were no murmurs, and the blood pressure was 110/70. The urine was clear, specific gravity 1.020, acid, there was no sugar or albumen but large amounts of acetone and diacetic acid. The Hb was 65 per cent, the red blood cells 3,630,000, leucocytes 9,140 with 88 per cent polymorphonuclears. The total plasma proteins were 4.60 grams per cent. She was given a transfusion of 500 cc of citrated blood and feeding was started by nasal catheter. The edema increased the watery stools were very numerous and she became lethargic. She was then given continuous vena clysis with approximately 2400 cc. of salt solution in one day. The edema increased rapidly and the plasma proteins fell to 4.34 grams per cent. The vena clysis was stopped. Salyrgan and theocin had no effect upon the edema. An attempt was then made to increase the amount of nourishment and to raise the daily intake of protein to 110 grams. When this was done improvement set in gradually, and though the diarrhea which was found to be due to Bac dysenteria Shiga persisted for months, the edema gradually subsided, the plasma proteins rose slowly and within six months the patient left the hospital entirely well.

Table 1 shows the relation between the de-

TABLE 1

gree of edema and the level of the plasma proteins.

It is to be noted in this case that the infusion of physiological salt solution was followed by an immediate increase in edema. This result serves as an illustration of the effect of accessory factors upon the production of edema in patients with hypoproteinemia. It has already been pointed out that edema may be increased in starvation by ingestion of excessive amounts of water or by the administration of sodium chloride or sodium bicarbonate, and it seems most probable that the anasarca was exaggerated in this patient by the administration of large amounts of salt solution. The comparatively slow recovery may well be attributable to the difficulty in feeding this patient sufficient quantities of food and to the difficulty in controlling diarrhea. With the continuous loss of water through the stools and on a salt poor diet, the patient became finally free from edema, while at rest in bed, even though the concentration of plasma proteins was slightly below the critical level at which edema is likely to occur.

The history of the next patient who was profoundly anemic, illustrates some of the most serious effects of malnutrition as well as the

fact that edema in such patients is not necessarily connected with the degree of anemia.

The patient was a married white woman of twenty-four (Unit 27215) who came to the Johns Hopkins Hospital on October 2, 1929 from Tennessee, complaining of diarrhea, stomach trouble and sore mouth, which she had had intermittently for three years and nine months. Previously she had been well and active though she had at times been nervous. Her best weight had been 140 pounds. Her present illness started after the birth of her youngest child on Dec 10, 1926. Fifteen days later her mouth became sore, her tongue fiery red and blistered and her mouth and gums swollen. These symptoms persisted for three months and then were accompanied by anorexia, abdominal pain, nausea, vomiting, excessive diarrhea, weakness and pallor, all of which lasted for six months. At the end of this time there was a complete remission of all symptoms for ten months. Her diet consisted largely of eggs, milk, and toast. In May 1929, about six months before admission the original symptoms re-appeared but in addition there were for the first time bleeding from the gums, tingling in the fingers and toes, cramps in the muscles of the legs, and during the latter part of her illness swelling of the hands and feet. She had eaten during these six months practically nothing except tea and toast, and there had been a loss of about forty pounds in weight. On admission to the hospital she was extremely pale and weak. The temperature was 102.5°. There was well marked anasarca with bleeding from the gums and hemorrhages in the fundi. The tongue was beefy red and showed vesicles. The lungs and heart showed nothing remarkable. The blood pressure was 102/58. The abdomen was distended and the liver readily palpable. The vibratory sense was preserved and the sense of position intact. The red blood cells were 850,000. Hb 27 per cent, lets 1280, and platelets 30,000. The red blood cells showed pronounced anisocytosis, poikilocytosis and macrocytosis. Except for the presence, occasionally, of traces of albumen the urine was normal. Wassermann reaction was negative. The gastric analysis showed free HCl after histamin, but none before.

The charts (figs 2 and 3) show the course of her illness.

It is to be noted particularly that the anasarca is marked, the anemia grave, the evidences of purpura quite marked, the diarrhea persistent for some days and that tetany occurred. The examinations of the blood showed that the non-protein nitrogen was remarkably low (16 mg per cent), the plasma proteins greatly diminished (3.95 grams per cent), and the calcium and phosphorus reduced (Ca 6.8 mg per cent, P 2.1 mg per cent). It was obvious that the patient had been deprived not only of proteins and vitamins, but of such minerals as calcium and phosphorus. The deprivation had come from partial starvation and perhaps to some extent also from loss of these materials through the stools. On a high calory diet containing 200 grams protein, to which was added liver extract, cod liver oil and large amounts of calcium and phosphorus, the patient improved rapidly. During one period of a few days the amount of salt in the diet was increased whereupon the edema became much more marked. When the salt was withdrawn the edema decreased rapidly. Over one period of twelve

common in many diseases of the gastro-intestinal tract Landis and Leopold²² have reported a case of tuberculous enteritis in which edema was associated with low colloid osmotic pressure of the plasma proteins Transfusions of blood and a high protein diet were followed by a subsidence of the swelling and a noticeable increase in the colloid osmotic pressure of the serum

I would now like to draw your attention to some rather unusual examples of nutritional edema The first case is one of amebic dysentery complicated by a remarkable degree of anasarca appearing during the course of the attack

The patient was a colored laborer forty seven years of age (Unit 45358) who was admitted to the Johns Hopkins Hospital on September 14, 1932 complaining of diarrhea of five months duration and swelling of the legs of two months' duration. Fifteen years previously he had had a similar attack of diarrhea at which time his legs were swollen. In the interval he had been quite well There had been no symptoms to suggest heart or kidney disease After a dietary indiscretion five months before admission he had suddenly developed a watery bloody diarrhea which had persisted up to the time of his admission to the hospital At the onset there was abdominal pain, but he had not had chills, and had not noticed fever or night sweats For three months he had had swelling, beginning in the ankles and extending up the legs until within a few days of admission it had involved most of his body During the greater part of his illness he had been up and about and at no time had he restricted his diet for he had eaten much the same food as when he was well He appeared to be a well-developed somewhat pale Negro with a temperature of 98.6°, pulse 70, respirations 18 He showed widespread anasarca with soft pitting edema over the legs, abdomen back, chest and arms and râles at the bases of the lungs The heart was normal in size, the sounds were clear except for a soft systolic murmur at the pulmonary area the blood pressure was 150/98 The spleen and liver were not palpable but there was evidence of ascites There was moderate anemia, the Hb being 68 per cent, the red blood cells 3,550,000 The leucocytes were 8,400 with 64 per cent polymorphonuclears The urine had a specific gravity of 1.011 showed no sugar, a faint trace of albumen and no casts The Wassermann reaction was negative The stools showed blood mucus and many active amebae histolyticae The total serum proteins were 3.77 grams per cent*

The chart (fig 1) shows in outline the course of the illness It is to be noted that the edema is associated with a remarkably low total plasma protein with great reduction in the plasma albumen The estimated colloid osmotic pressure of the plasma was only 11.12 mm of Hg compared with a normal of about 26 On rest in bed, a low residue salt-poor diet, containing 120 grams of protein, and a course of yatren, the improvement was rapid The diarrhea soon ceased, the edema subsided as the blood proteins increased, the anemia improved, and within twenty-four days after admission the patient

was practically well, the total proteins had increased to 6.39 grams per cent, a normal figure, and the calculated colloid osmotic pressure was doubled (21.47 Gm per cent) There appeared to be a close relationship between the low plasma proteins and the occurrence of anasarca in this patient On the other hand the manner in which the body was deprived of protein is not quite clear Although the man stated that he had eaten his customary amount of food including meat, the diet may have been somewhat inadequate It is more probable, however, that protein was not properly digested or was not absorbed in adequate amounts, for even the supernatant fluid of the stools was found to contain six grams of protein per liter Some protein must also have been lost in the blood in the stools

FIG 1 Case 1 Showing the changes in plasma proteins the variations in weight the loss of edema the total protein in the diet, the number of stools per day and the treatment.

In the next patient the cause for the protein deprivation was quite obvious

She was a white woman of fifty six (Unit 45759) who was admitted to the Johns Hopkins Hospital on October 8 1932, complaining of weakness, anorexia, diarrhea and sore tongue She had generally been very healthy until four months before admission when she had slipped and sustained a fracture of the neck of the left femur She was taken to a hospital, placed in a splint, and because of constipation given frequent enemata Food disagreed with her she had nausea and vomiting, and two months after her injury developed profuse and intractable diarrhea She ate almost no food became emaciated, and a few days before admission to the Johns Hopkins Hospital her tongue became very sore On admission she appeared quite ill with a temperature of 98° F, pulse 116 and respirations 20 She had lost much weight, but the legs were edematous The tongue was beefy red and showed small ulcers The lips and skin were very pale the lungs were clear to percussion and auscultation, the

*The plasma proteins were determined in a few instances by the refractometric method but as a rule Howe's method was employed and the estimations were made under the direction of Dr. Mary V. Bnell

Howe J E The determination of proteins in blood—A micro method J Biol. Chem. 49 109 1921

chloric acid. The case presents many features of interest and will probably be reported later in detail, but it serves at this time to illustrate the fact that the anemia was dependent upon the lack of liver whereas the edema, which was related to the hypoproteinemia, resulted from protein starvation.

In many forms of anemia and especially in pernicious anemia there may be moderate to severe grades of edema. Peters and Eisenman¹⁴ found that in this group of cases edema was quite regularly accompanied by a reduction of plasma proteins, though in some instances edema was prone to occur when the plasma proteins were at a comparatively high level. They remark upon the readiness with which these patients tend to develop edema. It has occurred to us in studying the appearance of edema in patients with pernicious anemia and idiopathic hypochromic anemia that in many instances accessory factors must be taken into account in these patients. As the anemia progresses whether this be pernicious anemia, posthemorrhagic anemia, or the idiopathic hypochromic anemia the patient becomes short of breath, experiences palpitation and presents many of the symptoms of mild congestive heart failure. This disturbance in the circulation might readily exaggerate a tendency to dependent edema in a patient in whom the colloid osmotic pressure of the plasma is so much reduced that it approaches the critical level. Frequently the edema subsides when the patients are placed at rest in bed.

So far we have considered the occurrence and control of edema exclusively in patients who are the victims of different forms of malnutrition and food deficiencies. Whether the patient happens to suffer from pernicious anemia, sprue, persistent diarrhea, different forms of chronic dysentery, or simply inadequate amounts of food, we find that the occurrence of edema is regularly associated with prolonged deprivation or loss of protein from the body and that the presence of edema is usually a reliable sign of protein starvation, and an indication that the patient needs large amounts of protein to repair the loss. The beneficial effects of increasing the protein in the diet and the detrimental effects of administering large amounts of water and sodium chloride are illustrated by the few cases that have been quoted.

It is known that the body is capable of manufacturing its plasma proteins with considerable rapidity, and that in animals, at least, it is difficult, even by starvation for several days to reduce the total amount of plasma protein.^{23, 24} Globulin is manufactured more rapidly than plasma albumen. The question has often arisen, however, as to whether hypoproteinemia may result from some interference with the formation of plasma proteins.²⁵ Myers and Taylor²⁵ have recently described a case in which they conclude that this unusual defect did exist. The

patient, a man of fifty-one, suffered from chronic edema associated with low plasma proteins, which were present in the usual ratio. There was no disease of the heart or kidneys. There was no loss of protein through the bowel. Since the feeding of a large quantity of protein, which was absorbed, did not raise the level of the plasma proteins, it was assumed that the defect lay in the inability of the body to construct plasma proteins in normal amounts.

Unfortunately we are quite ignorant as to the method by which the plasma proteins, with the exception of fibrinogen, are formed in the body. But since there is excellent evidence to show that fibrinogen is manufactured by the liver, the suggestion has often been made, based principally upon the experimental work of Whipple and his co-workers²³, that the synthesis of blood proteins may be in part, at least, a function of this organ. It has been repeatedly observed that the plasma proteins, and particularly the plasma albumen, may be reduced in cirrhosis of the liver.^{13, 14, 26, 27} Dr. Bordley, who has been interested in this subject, has furnished me with the data which he has collected in some of our cases of liver disease. It is found that of seven cases of cirrhosis of the liver, all of whom showed ascites and edema of the lower extremities, the total plasma proteins were well below normal in six, and were either at or below 5.5 grams per cent.

TABLE 2
CIRRHOSIS OF LIVER

No.	Edema	Ascites	Total P	A/G	Alb	Glob
1	++	++++	6.12	34/66	2.08	4.04

7	+++	+++	5.0			

in four (Table 2). In four cases in which the amounts of albumen and globulin were recorded, there was a reversal of the normal ratio, and even though the total plasma proteins were normal in amount, the plasma albumen was below normal and the calculated colloid osmotic pressure considerably reduced. The occasional recognition of definite subcutaneous edema in cases of acute yellow atrophy of the liver, many of which followed intravenous injections of arsenphenamine, led to an examination of the plasma proteins in some of these patients. Peripheral edema was noted in five out of fifteen of our cases. So far the plasma proteins have been determined in only six patients (table 3), three with and three without edema. In the three patients with edema the total plasma proteins were respectively 4.22 grams per cent, 4.12 grams per cent and 5.57 grams per cent. In the three cases without edema they were 5.94 grams per cent, 6.37 grams per cent and 7.41 grams per cent. In the last instance the plasma albumen was almost normal, 3.92 grams per cent, but in four

days (Dec 2-Dec 14) the protein intake was increased to 250 grams and the total calories to 4000. During this period there was an average daily retention of seventeen grams of nitrogen and a gain of weight of three kilos. She finally left the hospital in practically perfect health.

January, 1934 all her symptoms were exaggerated and, though she became rapidly weaker and paler and had dizziness and anorexia, there was no marked edema and only slight swelling of the ankles after exertion.

When she was admitted to the hospital for

FIG 2 Case 3 Showing changes in Hb RBC WBC platelets and reticulocytes during the course of treatment by liver extract on the first and second admissions

She remained well, eating a generous diet and taking three lbs of liver weekly, until July, 1932 when liver became distasteful to her and she stopped taking it, though she continued to eat other foods. In December, 1932 there was a

relapse of her previous symptoms, and though these were partially controlled by the use of ventriculin she gradually grew worse. After the second time on April 2, 1934 her condition was much as it had been on the last occasion except for the fact that there was no actual edema, but only a slight puffiness of the eyes. The anemia was great, and on April 3 the Hb was 29 per cent, the red blood cells 600,000, the leucocytes 1,650 and the platelets 60,000. The plasma albumen was 3.97 grams per cent, the plasma globulin 2.04 grams per cent, the blood calcium and phosphorus were normal (Ca 9.4 mg per cent, P 5.0 mg per cent). The gastric analysis showed after alcohol free HCl 5, and after histamine free HCl 48. The total plasma proteins were 6.03 grams per cent. On large doses of liver extract intramuscularly (4 cc No 343 every other day) and by mouth she improved with great rapidity and by May 21 the Hb had risen to 80 per cent and the red blood cells to 2,960,000.

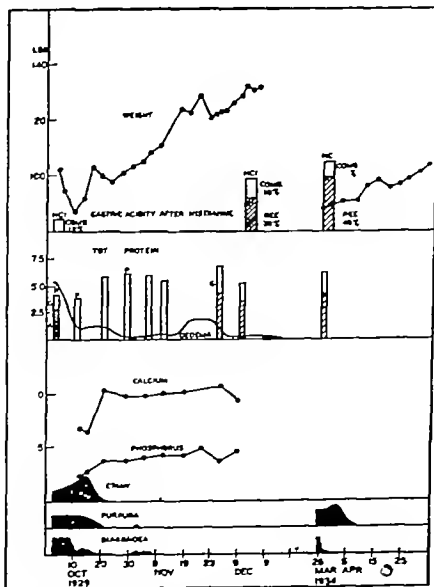

FIG 3 Case 3 Showing changes in weight, the plasma proteins, the variations in edema, the alterations in calcium and phosphorus of the blood and the course of the illness during the first and second admissions

relapse of her previous symptoms, and though these were partially controlled by the use of ventriculin she gradually grew worse. After

It is to be particularly noted that the most serious feature of the illness during the last exacerbation was this profound anemia of macrocytic type. There was also a marked reduction of platelets with purpura. Free hydrochloric acid was present in the gastric juice. There was marked loss of weight, and diarrhea, but no edema and the plasma proteins were normal. There was no conspicuous change in the blood calcium or blood phosphorus. The diet seemed to have been fairly adequate except for the absence of liver, which appeared to be absolutely essential to prevent anemia in this patient in spite of the fact that the gastric secretion contained fairly large amounts of hydro-

NEW ENGLAND BRANCH,
AMERICAN UROLOGICAL ASSOCIATIONTHE VITAL IMPORTANCE OF THE RELATION OF
HYPERPARATHYROIDISM TO THE FORMATION OF
CERTAIN URINARY CALCULI—AND ITS REMEDY*

BY RICHARD CHUTE, M.D.†

I WOULD like to say a few words on a subject which impresses me as being a true fundamental step forward in our knowledge and which I venture to prophesy in the near future will be considered by urologists as one of the most important advances made in a long time. The reason why I proclaim the importance of this matter with such assurance is that we have apparently found the definite cause for the formation of many calcium and phosphate urinary stones, especially the recurrent and multiple ones, and have also found the remedy. I refer to the rather recently discovered condition of hyperparathyroidism in relation to the very frequent formation of renal calculi in this condition. These remarks make no pretense of being either a complete description of hyperparathyroidism or a discussion of the various other factors such as infection or vitamin A deficiency, thought to be involved in stone formation, but purposely take up only hyperparathyroidism as it is related to the formation of calcium and phosphate stones. I have been fortunate enough to see a number of cases of hyperparathyroidism and to learn something about this comparatively new condition from a distinguished group of colleagues at the Massachusetts General Hospital, where more investigation and work on this condition has been done than in any other clinic in this country. The credit for the remarkable advances made is shared by the internists and the surgeons, with the lion's share going to the former,—Drs. Joseph Aub, Walter Bauer, and Fuller Albright, especially to Dr. Albright who by his very great knowledge, industry and zeal, has been the prime mover in the most recent phases of this work. At the present time there has been accumulated at the Massachusetts General Hospital a series of sixteen cases of hyperparathyroidism that have been operated upon and the abnormal tissue removed and proved histologically, the largest proved series in any one clinic in the world, I believe.

Hyperparathyroidism is a term used to describe a condition due to an excess of the internal secretion of the parathyroid glands. The source of this oversupply is found to be either a benign adenoma or hyperplasia of one or

more of the four little parathyroid glands, producing an excess of the internal secretion, known as parathormone. These glands, by means of this internal secretion, exercise a profound influence on the metabolism of calcium and phosphorus in the body, and in these cases of hyperparathyroidism with an excess of secretion, the blood calcium is raised, the blood phosphorus is usually lowered but not always, and there is a greatly increased amount of both calcium and phosphorus being excreted in the urine, associated with something which is of great interest to us of the urological fraternity, the frequent formation of calcium and phosphate stones. This stone formation is consequent to the tremendous concentration of calcium and phosphorus being excreted in the urine several times the normal amount which therefore has an abnormally great tendency to precipitate out as solid calcium phosphate and thus to form calcium phosphate stones, especially in an alkaline urine. In the Massachusetts General series, out of the sixteen cases, twelve (or 75 per cent) had stone formation in the urinary tract. Of course, since this calculus formation is due to a systemic disturbance, these calcium phosphate calculi tend to be recurrent, multiple, and bilateral, showing no particular favoritism for one kidney over the other. This is indicated by the fact that six (or 50 per cent) of these cases had bilateral calculi, and one of these cases had many recurrent bilateral renal calculi over a period of ten years. Another of these cases who was observed for six years, before the cause of his trouble was found and removed, was watched by x-rays in the act of forming renal calculi while he was under observation. He first entered with normal kidneys, normal urine and normal x-rays, but he gradually developed bilateral renal calculi and also calcification in the kidney cortex leading to severe and permanent kidney drainage. This latter is a very important and serious feature of this condition, because the formation of minute stones, concretions or calcifications in the tubules of the kidney cortex is not at all uncommon in hyperparathyroidism, and of course leads to severe and irreparable damage to the renal parenchyma and to the hopeless end-result of contracted, practically functionless kidneys. Figure 1 shows the x-ray picture of such a case in a man of thirty-three where generalized calcium deposits can be seen in the collecting tubules of both kidneys, each pyramid be-

From the Massachusetts General Hospital.

other patients in which the plasma albumen was determined it varied from 2.5 grams per cent to 2.1 grams per cent, figures which fall well below the estimated normal

There seems to be little question, therefore, that the plasma albumen may be considerably reduced in cirrhosis of the liver and in some cases of acute yellow atrophy of the liver. In the mild forms of jaundice, on the other hand, there

TABLE 3

ACUTE YELLOW ATROPHY

No	Edema	Total P	A/G	Alb	Glob	Fibrinogen
1	+	4.22	53/47	2.23	1.98	
2	++	5.57	38/62	2.11	3.45	Decreased
3	++	4.12				
4	0	5.94	39/61	2.31	3.61	
5	0	7.41	53/47	3.92	3.48	
6	0	6.37	45/55	2.56	3.49	Decreased

seems to be little or no alteration in the plasma proteins^{13, 14}. What the significance of the reduction of plasma albumen in cirrhosis of the liver and acute yellow atrophy may be, it is not possible at the present time to state. Patients with cirrhosis of the liver are often poorly nourished.

I have tried to trace for you the study of one common symptom in an interesting group of diseases that arise from improper nutrition. These deficiency states, as we have seen, may appear in the most varied forms, either as well-defined diseases, or as a combination of symptoms. One symptom which is common to many of them is edema, sometimes progressing to a marked anasarca, and it was our intention to enquire into the cause and relief of this symptom.

It can be shown that protein is often grossly deficient in the diets of patients who suffer from these disturbances of nutrition. Diarrhea in addition is not uncommon so that the protein deficiency may be still further increased by the difficulty of absorbing protein through the gastro-intestinal tract or by the constant loss of small quantities of food protein and of blood in the stools. The deprivation of protein eventually leads to a lowering of the plasma proteins, which in turn predisposes to the formation of subcutaneous edema or is actually the cause of it. Accessory factors, such as the ingestion of considerable amounts of sodium chloride and water, the upright position and mild degree of congestive heart failure may precipitate edema or exaggerate it, but the underlying cause rests usually in the protein deficit. This particular form of deficiency may be relieved by feeding adequate or, if necessary, excessive amounts of protein. When this can be accomplished the plasma proteins may return to their normal levels and the edema may rapidly disappear.

tively identified only by a frozen microscopic section on the spot. The size apparently has more or less to do with the amount of metabolic disturbance produced. A great deal of credit is due to Dr Oliver Cope and especially to Dr Edward Churchill of the Massachusetts General Hospital for successfully performing these operations which can be very difficult indeed. They have recently written an admirable article describing their technique and results in eleven cases of this series².

I would like to report briefly one new and interesting case in a married woman who was forty-two years old when she was first seen by my father in 1924, ten years ago. At that time he performed a left nephrectomy for calculus pyelonephrosis, the left kidney having been completely destroyed by one large stone and nine smaller ones throughout its substance.

Although the patient started passing gravel within two months of leaving the hospital she got along reasonably well for the next few years until 1930 when she again had trouble and a stone as big as a five-cent piece and three times as thick was removed from her remaining kidney. Analysis of this stone showed it to be made of calcium phosphate. A few months later she passed a small phosphate stone herself, and a year later another one. Last spring she was having trouble again and x-rays showed a small stone shadow in the lower calyx of her kidney. I had my eye out for cases of hyperparathyroidism and took her to Dr Albright who made the diagnosis of hyperparathyroidism on the basis of a high blood calcium (12.5 mg.) a low blood phosphorus and her history of repeated formation of calcium phosphate stones. She was strongly urged to be operated on but decided to go home to think the matter over. However the matter was soon taken out of her hands because her stone moved up to the ureteropelvic junction and blocked off her kidney and she came flying back into the hospital with anuria, fever, chills, vomiting, etc. After an unsuccessful attempt to drain her solitary kidney with a ureteral catheter an emergency nephrostomy had to be done to save her life. The stone could not be located at this operation and not too much time was wasted in looking for it as the patient was in a critical condition. After a few stormy days during which she had many crises she came along nicely and went home wearing a nephrostomy tube. She returned after three months and Dr Churchill removed a parathyroid tumor twice the size of a green pea. At the time of operation all the urine for twenty-four hours beforehand and twenty-four hours afterward was kept and analyzed for the excretion of calcium and phosphorus. The twenty-four hour specimen after the operation showed the expected drop in the direction toward normal of the amount of calcium and phosphorus being excreted in the urine and also her blood calcium and phosphorus both moved in the direction of normal. Meanwhile the stone had been moving slowly down the ureter and following several cystoscopic manipulations it was passed a few days after the parathyroid operation. The nephrostomy tube was removed a few weeks afterward, the wound healed up nicely and the patient has been well ever since with her calcium and phosphorus values approaching normal. She has made no more stones or gravel and I am confident that she will never do so now that her urine is no longer being flooded with calcium and phosphorus.

The first of the cases of hyperparathyroidism with urinary stone was operated upon seventeen months ago and since then a number of others, and no stones have recurred in any of these cases all of whom have been followed very carefully and their calcium and phosphorus values have remained normal.

Fifty per cent of these cases of hyperparathyroidism have had calculus formation or calcification in the urinary tract visible by x-rays. This percentage is undoubtedly too large to be true in general but is due to the fact that patients come in to the hospital for calculus trouble and then are found to be suffering from hyperparathyroidism. There are undoubtedly a great many undiagnosed cases of hyperparathyroidism walking around who are considered to have rheumatism or some orthopedic condition. Stones especially bilateral or recurring ones, should always at least bring up the question of an underlying hyperparathyroidism. It is now routine at the Massachusetts General Hospital for all stone cases to have estimations of their blood calcium and phosphorus and in this way a number of cases of hyperparathyroidism have been detected and remedied, thus preventing recurrence of their stones or future dangerous calcifications in their kidney tubules. To guard against this latter life shortening occurrence which can do the kidneys irreparable damage, it is most important to discover and cure all cases of hyperparathyroidism before this condition sets in.

This new and stimulating work concerns the formation of calcium and phosphate stones only, but it opens up an endocrinological and systemic point of view and method of attack which may give help in the further study of the causes of formation of urinary calculi of other compositions.

In conclusion, I would make an earnest plea to every urologist to consider the possibility of an underlying hyperparathyroidism in every case of urinary lithiasis, and I feel strongly that it is our duty to these patients whose well-being has been entrusted to us to give them the benefit of this newer knowledge by a careful estimation of their fasting blood calcium. Probably most of these calcium estimations will be normal, but they should not be counted as labor lost but as a duty well performed because eventually in this way, as has happened at the Massachusetts General Hospital, many patients suffering from hyperparathyroidism will be able to be diagnosed and cured, patients who otherwise might have gone on to the formation of more stones or of calcifications in the kidney tubules, resulting in irreparable damage to the kidneys and premature death.

ing represented by a clump of minute calcium concretions. This case has been previously reported by Albright, Baird, Cope and Bloomberg¹. Recently Albright showed me in his laboratory definite calcium phosphate casts of the kidney tubules in one of these hyperparathyroid cases whose urine was loaded with calcium phosphate. These casts could be dissolved by acidifying the urine. On account of the abnormally great excretion of calcium and phosphorus, these two elements are drained away from the skeleton which consequently becomes demineralized, and weaker, and casts a less dense

thing over 11½ milligrams is very suggestive. The average in the sixteen cases in the Massachusetts General series was 13.9 milligrams. The only adequate remedy for hyperparathyroidism to date is the surgical removal, either complete or subtotal, of the adenomatous or hyperplastic gland tissue. X-ray treatment has been tried without success. Surgical resection results in checking the hypersecretion back to a normal amount, which in turn brings the calcium and phosphorus in the blood back to normal and decreases the excretion of calcium and phosphorus in the urine down to normal, thus relieving

FIG 1

x-ray shadow. As a result of this condition there occur fractures following minimal trauma, cysts in the bone, epulis of the jaw, and other manifestations which cannot be described here. The subjective symptoms of hyperparathyroidism are not always very marked, and are apt to be dependent on the decalcification of the skeleton, often taking the form of generalized aches and pains in the bones and joints, weakness of the legs, and naturally loss of weight. Some cases are always thirsty and drink and urinate a lot, and have even been diagnosed as diabetes insipidus. The diagnosis rests fundamentally on the finding of a high blood serum calcium. The normal value for this is about 10 milligrams per 100 cubic centimeters of blood, and any-

the urinary stream of the burden, which often proves too heavy for it, that of carrying so abnormally large and heavy a load of calcium and phosphorus that some of it is apt to fall off and be dumped somewhere along the line of the urinary passages. The operations for the removal of these parathyroid tumors are often most tedious and trying. In a difficult case the whole posterior aspect of the thyroid gland, the neck and sometimes even the mediastinum must be carefully and bloodlessly dissected and methodically explored for a tumor whose size and location the operator cannot know beforehand. Occasionally the tumor may be the size of a small hen's egg, but more often it is very much smaller, and sometimes it is so small that it can be pos-

DENERVATION AND DISPLACEMENT OF THE URETER
FOR EXAGGERATED RENAL COLIC*

With A Report of a New Case

BY THOMAS N. HEPBURN, M.D.†

An intractable renal colic is occasionally encountered especially in the female which cannot be explained on any other hypothesis than a spasm of the circular muscles of the ureter pelvis or calyces but chiefly of the ureter.

Little has been known of the nerve supply of the kidney and ureter. In blind despair, various clinicians have tried relieving these patients by denervation operations. Professor Papin of France reported his operation for nephralgia by severing the sensory nerves running on the surface of the renal artery to the kidney.

Wharton reported two cases in 1930, in which through a suprapubic abdominal incision, he denervated the ureter beginning 6 cm. from the bladder and going to opposite the fourth lumbar vertebra. He dropped the ureter back into its bed.

That same year I reported my operation with two cases in which I denervated the whole ureter through a retroperitoneal approach and displaced the ureter laterally, at least two inches from its old bed, in an effort to retard the possible regeneration of this nervous mechanism. No one of these clinicians was aware of the others' work.

Since the report of these cases, Wharton by an elaborate research dissection with the cooperation and assistance of Streeter found

- 1 That the ureter received a nerve supply which is different from the innervation of the kidney and bladder
- 2 That nerves go directly to the ureter from
 - (a) The lowest renal ganglion at the upper end of the spermatic plexus
 - (b) The abdominal sympathetics, aortic, hypogastric and pelvic plexuses
- 3 That there is a connection between the ureteral innervation and plexuses that supply the ovary and testis

Andler had previously in 1925 experimented on animals showing that denervation of the ureter did not disturb its functional peristalsis and that no atony, hydro-ureter or stricture resulted.

Fromolt in 1928 by animal experimentation showed that the ureter could be liberated from the kidney pelvis to the bladder without im-

pairing its nutrition because its blood supply came from the renal, vesical and uterine arteries which had a sufficiently rich anastomosis within the ureteral walls to keep it satisfactorily nourished.

Lee in 1930 experimenting with cats showed that the cervical sympathetic nerves could regenerate in thirty-five days after gaps of one inch had been resected.

None of this animal experimental work had been reported when the first denervations of the human ureter were done.

Papin's operation of cutting the sensory fibers to the kidney is based on the presumption that there is no remediable cause for the pain, and the best we can hope to do is to relieve our patients from its sensory effects. Wharton's and my operation are based on the theory that the nephralgia is due to spastic obstruction of the ureter and that if we can relieve the kidney of the back pressure resulting from this spastic obstruction there will be no pain. Our operations have one great advantage over Papin's, in that the pathological process, so far as the kidney is concerned, is relieved.

Papin's operation does not stop the spasm, but only the renal pain resulting from the spasm. Ureteral denervation stops spasm, but renal pain will still result from any other type of ureteral obstruction.

If one should apply the conclusions from working on the sympathetic cervical nerves of the cat to the human beings, that they can regenerate in thirty-five days and bridge defects in continuity of an inch, the regeneration of the nerves of the denervated ureter should be completed in a few months' time, and the spastic disability re-established. There has been no recurrence of pain in Wharton's cases. So possibly this regeneration is not effected in human beings, again proving that animal experimental findings should not be blindly applied to them.

Without having any experimental work upon which to base this conclusion, I added the displacement factor to my denervation operation. One case has gone eight years and another one year without any return of spasm. The displacement factor has a mechanical advantage in that it takes up any redundancy which may have developed as a result of the obstructive and inflammatory processes, thereby improving the drainage of the kidney pelvis and facilitating recovery from pyelitis.

I freely admit I am not at the root of the

PYELO-URETERITIS CYSTICA*

BY WALTER D BIEBERBACH, M.D.†

I WISH to report the following case of pyelo-ureteritis cystica.

The patient was a forty-two year old married housewife, born in Poland. She had two admissions to the hospital, the first in November, 1931, at which time she complained of pain in the left kidney region. Three days later she had an attack of hematuria. The severe pain subsided with the appearance of blood in the urine and became duller in character accompanied by headache. Gradually the pain and bleeding subsided and the patient was free from symptoms for two or three months. Later they have recurred more frequently and the severity of the attacks and hemorrhage have increased. Her physical examination was negative except for slight tenderness on deep palpation at the left costovertebral angle, no mass could be felt.

Following are the cystoscopy and x ray report at the time of the first admission. "Kidneys outlined, normal in size and position. Catheters reach level of third transverse process. No calculi were seen. Bilateral ureteropyelograms show very small calices on the right with no filling defects. The ureter is dilated to a maximum width of 1 cm above the sacro-iliac level. The lower portion is not well shown. On the left side the pelvis and calices were within normal limits. The ureter shows an apparent right angle kink with a hiatus amounting to nearly 1 cm just above the third transverse process. There is very little dilatation. The ureter below the sacro-iliac level is not well shown. This examination suggests partial obstruction of the ureters on both sides, that on the right near the sacro-iliac level and on the left in the region of the kink. The cause is not apparent and nonopaque calculi must be considered. The general cystoscopic findings in the bladder were relatively negative except for some congestion of the bladder mucosa. No apparent obstruction was felt to No. 7 x ray catheters as they were passed to the pelves of the kidneys. Bladder specimen of urine showed a slight trace of albumin, no sugar, rare rbc, frequent wbc, squamous epithelial cells and bacteria. A culture showed nonpathogenic Gram negative bacilli. The right kidney sediment contained rare rbc with occasional wbc. Culture showed nonpathogenic Gram negative bacilli. A dye injected intravenously appeared on both sides in twenty minutes. Blood chemistry gave sugar 120 mgs per 100 cc, non protein nitrogen 30.0 mgs per 100 cc.

The patient was discharged with a diagnosis of partial obstruction of left ureter due to kink, with a question of calculi.

On January 31, 1933 the patient was readmitted to the Urological Service for study. Her symptoms were essentially as on her first admission but increased in severity. She stated that following her last cystoscopy she was free from symptoms for two months.

She was cystoscoped with the following findings: "No residual urine. Bladder capacity 300 cc." Plain and injected pictures were made, 12.5 per cent sodium iodide being used for the injection. The x ray report was as follows: Examination practically identical with that made in November, 1931 both ureters being dilated above the sacro-iliac level. The left ureter showed numerous small vacuoles that probably represent bubbles. No calculi are

shown in the tract. Because of the alleged bubbles intravenous pyelograms were made and these also showed two vacuoles at the level of the third lumbar transverse process. Diagnosis: Papillomatous or similar growth.

On February fourteenth it was decided that an exploratory operation was indicated under ether anesthesia. The kidney and ureter were removed. The specimen showed numerous mucosal cysts, 2 to 3 mm in diameter, in the kidney pelvis and ureter. Pathological diagnosis: Pyelo-ureteritis cystica.

In January 1934, one year after operation, the patient was checked up by cystoscopy and the report is as follows:

Urethra and external genitals normal. Bladder contains no residual urine. Capacity 300 cc. Studied throughout the bladder mucosa were many groups of small cysts, each group containing from four to five small transparent cysts about the size and shape of a split taploca. Around the base of each cyst was a small, bright red inflammatory ring which contacted with the bladder mucosa. In between the cysts was normal clear bladder mucosa. This type of cyst involved the entire bladder except the trigone. The trigone was thickened with bulbous edema. The upper and lateral surfaces of the internal sphincter were somewhat irregular and hanging from the left upper lateral margin was a small pear shaped cyst which was transparent. The right ureteral orifice is in normal position, imbedded in thickened mucosa. It was easily catheterized with a No. 7 x ray catheter and drained clear yellow urine freely.

The pelvis was injected with 10 cc 12½ per cent sodium iodide and ureteropyelograms were taken. The ureter was slightly dilated, also the renal pelvis. However these were not enlarged over the last x ray pictures. No vacuoles or air pockets were observed in the ureter. The ten minute emptying time showed no residual. Intravenous indigo-carmin appeared in good concentration in two and a half minutes. A collected specimen of urine from the bladder showed a slight trace of albumin, no sugar. Reaction acid. Sediment showed a few white blood cells and rare red blood cells. Culture no growth.

Specimen from the kidney showed slight trace of albumin, no sugar, acid in reaction. Sediment showed many white blood cells and rare red blood cells. Culture no growth. Guinea pig inoculated for TB was negative. Blood chemistry, non protein nitrogen 27.3 mgs. Blood smears all within normal limits.

There was no precedent in the literature advising operation in a case such as this. The patient's symptoms persisted unabated after the first cystoscopy. It seemed, therefore, that operative treatment was the only method of procedure. At the time of operation the exact diagnosis was not known, but in the presence of multiple tumors in the ureter it seemed advisable to remove the ureter and kidney. We recognize the possibility of the occurrence of the same condition on the other side. The patient to date, one year after her operation, is free from symptoms, and no increased pathology has invaded her remaining right kidney or ureter.

The above is an abstract from an article which will appear in *The American Journal of Roentgenology* in the near future with illustrations.

*From the City Hospital, Worcester.
Read at the meeting of the New England Branch of the American Urological Association, February 15, 1934.

†Bieberbach, Walter D.—Urologist, Worcester City Hospital.
For record and address of author see This Week's Issue, page 1297.

Operation—April 21, 1933 A left lumbar incision was made over the left kidney which was decapsulated and slung up in high position. From this incision the ureter was denervated down as far as a hand could safely reach.

A left McBurney incision was then made and the ureter exposed and denervated from the pelvic brim

FIG. 3. Nine months after denervation and displacement of the ureter.

down to within 9 cm. of the bladder and sutured well out on the lateral wall.

The lower end of the ureter was denervated through a midline suprapubic incision and retroperitoneal approach.

It is now nine months since her operation. She has had no renal colic. Cystoscopy now shows no pus from the catheterized urine and the bladder has cleared up.

Unfortunately, this patient got a periureteral infection which made her convalescence very annoying, several residual abscesses having to be drained. At one time the external pressure on the ureter of one of these abscesses caused enough obstruction so that this woman had distinct renal pain. This pain was relieved on drainage of the abscess. The conclusion to draw from this observation is that the denervation of the ureter relieves renal colic only by making ureteral spasm impossible and that any other pathology causing ureteral obstruction may produce renal colic.

CONCLUSIONS

1. Intractable renal colic in cases where no obstructive cause can be found may be due to spastic obstruction of the ureter. Denervation and lateral displacement of the ureter is a logical surgical procedure in such a condition. Another clinical case is presented to support this contention.

2. The claim is made that denervation is more completely done from the retroperitoneal approach, and that the added factor of lateral displacement makes less probable the regeneration of the spastic nervous mechanism and relieves any redundancy which may have developed in the ureter, thereby improving drainage of the renal pelvis and relief from pyelitis.

3. While it is recognized that spastic ureteral obstruction is doubtlessly a very common cause of renal colic in both sexes, the extreme spasms that require denervation are quite rare, and in all reported cases they have been found in women. Wharton's anatomical dissections revealing a connection between the sympathetic nerve supply of the ovary, testis and the ureter would seem to give a sound neurological mechanism to substantiate the hypothesis of a probable sexual foundation for these severe spasms. That they occur more frequently in women than men is because sexual emotional defeat occurs more often in women than in men.

RENAL SYMPATHECTOMY*

Report of Two Cases, Including One Fatality

BY ERIC STONE, M.D.†

I HAVE the temerity to report such a small series of cases because of the disastrous outcome of the second case. This has the dubious distinction of being the only recorded fatality for this operation as there was no mortality in

the group of thirty-four cases I was able to find in a review of the literature.

CASE I. E. P. female, aged 31 years. Record No. 2806. In June 1932 the patient passed a catheter into her uterine cavity to produce an abortion. In July she had a bilateral salpingo-oophorectomy and supravaginal hysterectomy performed. In September 1932 she began to have a series of attacks occurring about once in ten days, marked by acute left renal and ureteral pain sufficient to incapacitate her to the extent that she had to give up all employment. The attacks were all identical, simulating

*From the Urological Service of the Charles V. Chapin Hospital.

Read before the New England Branch of the American Urological Association, February 15, 1934.

†Stone, Eric—Surgeon in Charge, Urological Service, Charles V. Chapin Hospital, Providence. For record and address of author see "This Week's Issue," page 1297.

pathological picture when I am denervating the ureter. The cause of the spasm should be sought and if possible cured without operation. I am theorizing knowingly when I picture this cause as an emotional storm which lets loose a flood of nerve impulses too great to be carried by the ordinary conduits to the region from which the storm gathered, but must overflow to adjacent territory and involve neighboring structures. The sympathetic connection Wharton found between the ovary and testis and the ureter seems to me suggestive of a basis in some sexual emotional defeat. Its dominant finding in women I explain by the greater occurrence of sexual emotional defeat in women than in men. Dr Hunner's experience when he thought he was finding so many strictures in women, supports this theory.

There is no reason why emotional overflows may not have other than a sexual basis and result in ureteral spasm. I have seen many of them but to a lesser degree of severity. Ureteral colic due to spasm is not uncommon after an exciting meeting at a board of directors, or following an emotional platform oration. These spasms pass off more easily.

In order to add to the clinical material on this subject, I present the following case.

Miss Ruth S. first consulted me eighteen years ago when she was nineteen years of age because of pain in her right kidney region. Her appendix had been removed at seventeen. Cystoscopy at that time revealed no demonstrable pathology, and I made a diagnosis of sexual neurosis with ureteral spasm.

Painful attacks continued over a period of years. This patient was studied in various clinics, and besides developing a severe urinary infection no demonstrable pathology could be demonstrated. Her menses were always normal and the vaginal examination was negative. Her disabilities from these right renal attacks were so terrific that finally her family physician and surgeon did a right nephrectomy in February, 1932, that is sixteen years after the onset of her symptoms.

This relieved the patient for a few months only. The attacks then began occurring in the left kidney. The patient still had a bad chronic cystitis and had developed a left pyelitis with four plus pus cells from the kidney pelvis.

Her attacks were as often as once in ten days and were so severe that three or four grains of morphine would not control them. Avertin given rectally over a period of three and four days would not break the attack. Once a doctor had an anesthesiologist stay with her for twenty-four hours trying to keep her under ether anesthesia, but as soon as she would get out of the anesthetic, the pain would recur.

I saw her in 1933 for the second time in seven years. When she came to my care at the Hartford Hospital she was running a temperature from 101 to 106°. Her bladder was violently inflamed. Catheterized urine from her left kidney showed four plus pus cells. The functional capacity to excrete indigo-carmin was good. The ureteropyelogram is shown here. (See fig 1.) There is certainly nothing in this picture to explain the terrific renal colics to which this woman was subject. A diagnosis of spastic ureteral obstruction was made and a denervation operation decided upon.

FIG 1. Drawing of displaced ureter after it had been removed from its original bed through a retroperitoneal approach.

FIG 2. Before displacement and denervation of ureter.

Operation—April 21, 1933 A left lumbar incision was made over the left kidney which was decapsulated and slung up in high position. From this incision the ureter was denervated down as far as a hand could safely reach.

A left McBurney incision was then made and the ureter exposed and denervated from the pelvic brim

FIG. 2 Nine months after denervation and displacement of the ureter

down to within 9 cm. of the bladder and sutured well out on the lateral wall.

The lower end of the ureter was denervated through a midline suprapubic incision and retroperitoneal approach.

It is now nine months since her operation. She has had no renal colic. Cystoscopy now shows no pus from the catheterized urine and the bladder has cleared up.

Unfortunately, this patient got a periureteral infection which made her convalescence very annoying, several residual abscesses having to be drained. At one time the external pressure on the ureter of one of these abscesses caused enough obstruction so that this woman had distinct renal pain. This pain was relieved on drainage of the abscess. The conclusion to draw from this observation is that the denervation of the ureter relieves renal colic only by making ureteral spasm impossible and that any other pathology causing ureteral obstruction may produce renal colic.

CONCLUSIONS

1 Intractable renal colic in cases where no obstructive cause can be found may be due to spastic obstruction of the ureter. Denervation and lateral displacement of the ureter is a logical surgical procedure in such a condition. Another clinical case is presented to support this contention.

2 The claim is made that denervation is more completely done from the retroperitoneal approach, and that the added factor of lateral displacement makes less probable the regeneration of the spastic nervous mechanism and relieves any redundancy which may have developed in the ureter, thereby improving drainage of the renal pelvis and relief from pyelitis.

3 While it is recognized that spastic ureteral obstruction is doubtlessly a very common cause of renal colic in both sexes, the extreme spasms that require denervation are quite rare, and in all reported cases they have been found in women. Wharton's anatomical dissections revealing a connection between the sympathetic nerve supply of the ovary, testis and the ureter would seem to give a sound neurological mechanism to substantiate the hypothesis of a probable sexual foundation for these severe spasms. That they occur more frequently in women than men is because sexual emotional defeat occurs more often in women than in men.

RENAL SYMPATHECTOMY*

Report of Two Cases, Including One Fatality

BY ERIC STONE, M.D.†

I HAVE the temerity to report such a small series of cases because of the disastrous outcome of the second case. This has the dubious distinction of being the only recorded fatality for this operation as there was no mortality in

the group of thirty-four cases I was able to find in a review of the literature.

CASE I E. P. female aged 31 years. Record No. 2806. In June 1932 the patient passed a catheter into her uterine cavity to produce an abortion. In July she had a bilateral salpingo-oophorectomy and supravaginal hysterectomy performed. In September 1932 she began to have a series of attacks occurring about once in ten days marked by acute left renal and ureteral pain sufficient to incapacitate her to the extent that she had to give up all employment. The attacks were all identical simulating

*From the Urological Service of the Charles V. Chapin Hospital.
Read before the New England Branch of the American Urological Association, February 15, 1934.

acute hydronephrosis except that at no time was the urine collected from the pelvis found to be under pressure. The attacks were so violent that various local physicians called in during attacks sent her to the hospital fourteen times in eleven months. Complete urological examinations were made on four of these admissions and no demonstrable urinary tract pathology could be discovered. The pyelograms shown in Plate I were made during an at-

PLATE I Case I. Pyelogram showing normal calyces pelvis and ureter on the left the affected side; symptomless hydronephrosis on the right.

tack, on her sixth admission, and appear perfectly normal as do all other plates.

A knowledge of a bad psychoneurotic background and the emotional stimulus bringing on most of her attacks, lead to an investigation of her vegetative nervous system. More careful history taking revealed frequent attacks of urticaria, dyspnea, palpitation, recurrent intestinal colic and marked car sickness. An adrenalin test carried out on her last admission gave a marked sympathicotonic reaction (Chart I).

A composite of various physical examinations gives several significant findings, chiefly of a negative nature. During the attacks there was usually a tenderness over the left kidney region both anteriorly and posteriorly, but no muscle rigidity or inability to palpate the organ. The palpebral fissure was widened and the pupils dilated. Tachycardia was a constant finding. The gag reflex was increased and transitory areas of neurogenic hyperemia were usually present. The thyroid was not palpable nor could any abnormal impulse or bruit be made out in this region.

On August 8, 1933, under spinal anesthesia, the left kidney was exposed through an upper left rectus incision, the entire procedure being carried out extraperitoneally. The ureter was stripped of all its investments for a distance of 5 cm. The pedicle was freed and the vein and artery which bifurcated at the hilum only were easily stripped of all their coverings for a distance of 3 cm. The kidney was re-

placed in its bed and the wound closed around cigarette drain. The postoperative recovery was easy, being unaccompanied by any fever, nausea, or distention, and marked by less than the usual pain.

The patient was discharged on the sixteenth postoperative day. Two weeks later she resumed her work as a waitress and when last seen, January, 1934, had suffered no recurrence of the pain.

CASE II. M. I. O., female, aged 41 years. Record No. 2969. In May, 1931, the patient fell down a flight of stairs, suffering a mild concussion and multiple bruises. She was well until July 10, when she fell while standing on the floor, apparently having fainted. The next day she had a sudden attack of pain in the right kidney region lasting fifteen minutes and sufficiently severe to cause her to roll on the floor in agony. A second attack occurred two days later, and during the next three weeks, there was at least one attack a day, sometimes as many as four. Between the attacks she felt perfectly well. Once or twice after an attack, a few small red specks were noted in the urine and at various times, occult blood was found, but except for this and some frequency of micturition for a few hours after each attack, there were no urinary symptoms.

She was admitted to the hospital August 14, 1933. The next day a complete urological examination was done. A Fr. No. 18 stricture of the urethra was found and was readily dilated to Fr. No. 26. Both ureteric orifices were of golf-hole type and were fibrotic. The urines from both kidneys were sterile and the function of the kidneys normal. As was demonstrated by both retrograde and later by intravenous urography the kidneys and ureters were normal except possibly for a moderate hyperactivity of the right pelvis (Plates II and III).

In view of these negative findings and with the preceding case in mind her past history was reviewed for sympathicotonic symptoms. It was found that she had suffered from various gastro-intestinal disturbances for many years, with various diagnoses ranging from ulcer to chronic appendicitis. Indeed, in June 1932 her appendix had been removed and two weeks later a cholecystectomy was done. Pathologically, the appendix was normal, as was the gall bladder. These procedures gave her only slight relief. In youth, she had had recurrent long periods of bilateral neurogenic eczema, extremely resistant to local treatment, but at times disappearing spontaneously. Allergic vomiting had been present in childhood and infancy. Car sickness had always been marked. An adrenalin test gave a markedly sympathicotonic curve (Chart I).

Physical examination was essentially negative except subjective tenderness anteriorly over the lower pole of the right kidney and upper third of the ureter. There was no costovertebral tenderness at any time nor was the kidney palpable. The thyroid could not be made out. From August 17 to November 9 she was treated orally with calcium gluconate and parathroid tablets and received at four-day intervals intramuscular injections of acecollin. Once in ten days the right ureter was dilated, after four such instrumentations it was easy to pass a No. 12 bulb catheter into the pelvis.

During the month of October the attacks dropped from three or four in a day to an average of one in four days and those that occurred were much less severe. But during the latter part of the month she developed hyperesthesias and paresthesias particularly of the neck and arm and she was troubled with nausea and occasional vomiting. It was deemed wise to discontinue medication on which the attacks recurred in their original frequency and vigor. The day of her readmission she had three attacks, two occurring during the night in the hospital.

On December 2 at 8 A.M., a right renal sympathectomy was done under spinal anesthesia. A right lumbar oblique incision was made, exposing an apparently normal kidney and ureter. The ureter for 4 cm and the pedicle were divested of all their

fluid intake resulting in a normal urine output, freely voided made artificial administration of fluids unnecessary. During the first 48 hours the abdomen was soft and flat, flatus being expelled readily. During this period the pulse remained steadily between

Investments a decapsulation was carried out and the organ was suspended according to Demings technique. The wound was closed in layers around a cigarette drain. The patient was returned to her bed in excellent condition. Except for a one-minute spell of retching a few minutes after administration, the anesthesia had been uneventful. The operation took fifty-five minutes to complete.

During her postoperative life there was at no time any nausea or vomiting. An excellent oral

100 and 110 respiration and temperature were normal although the temperature reached a peak of 101° the first day. It continued normal after the second day. There was so little discomfort that she received only one injection of morphine postoperatively that given on the day of the operation. Her condition was considered so fine that at the end of twenty-four hours she was removed from the recovery room.

When seen by the house officer at nine in the

acute hydronephrosis except that at no time was the urine collected from the pelvis found to be under pressure. The attacks were so violent that various local physicians called in during attacks sent her to the hospital fourteen times in eleven months. Complete urological examinations were made on four of these admissions and no demonstrable urinary tract pathology could be discovered. The pyelograms shown in Plate I were made, during an at-

But during the latter part of the month she developed hyperesthesias and paresthesias particularly of the neck and arm and she was troubled with nausea and occasional vomiting. It was deemed wise to discontinue medication on which the attacks recurred in their original frequency and vigor. The day of her readmission she had three attacks, two occurring during the night, in the hospital.

might be responsible for the symptoms, that they performed a ureteral sympathectomy or a renal sympathectomy. In other words they acknowledge, I think, that they interpreted their urological studies as showing nothing very definitely wrong with the kidney and yet they went ahead and did a renal or ureteral sympathectomy. How can one be sure? I am asking for information because I may have a similar case. How can one be sure that when he does a sympathectomy on the kidney or the ureter that it is really the cause of all the trouble that it may not be some other lesion or something in addition to that. In other words, what is the thing that crystallizes your judgment in doing such an operation?

C. L. DEMING, M.D. I am very much interested in renal sympathectomy. During the past year I have done two cases. Both of them were nurses about the age of 30. They both had been watched for some time and had been cystoscoped several times. Both had been thoroughly studied and we endeavored to formulate some idea as to what combination of symptoms and cystoscopic findings would indicate the procedure for a renal sympathectomy. We have two other cases on whom I think a sympathectomy is indicated. From the study of these four cases two of whom have been operated on with complete relief of symptoms, one for nearly a year, the other two and a half months (the latter is too short a period for a report of complete success) we endeavored to glean four or five factors which might lead us to the ideal sympathectomy case. The factors are these:

1. A long history of periodic attacks of pain which may be localized in the ureteral region referred toward the bladder. These attacks of pain are very difficult to relieve even after heavy doses of morphine. Ureteral catheterization did not seem to give relief but for a short period of time.

2. These cases all show a very painful ureteral catheterization. All of them will complain of severe pain as you pass a catheter up the ureter.

3. As one passes the catheter no matter whether it is No. 4, 5 or 6 the ureter always rolls with the catheter. It seems to be in a spastic condition. Even after these ureters have been dilated with large bougies and then a small No. 4 catheter is passed the ureter hugs it tightly and rolls with the catheter.

4. All of our cases showed normal urograms without any evidence of obstruction but there was a delayed emptying time a factor which I have not seen emphasized. Ten, twelve or fifteen minute emptying time films show a residue in the pelvis. We do not know what this means for we rarely see retained material within the pelvis and ureter unless there is an obstruction or ptosis.

E. L. PEARSON, M.D. I have been much interested in the treatment of nephralgia or kidney pain for which there is no obvious cause. In the last two and a half years I have done three operations for this condition with some satisfaction. The great majority of these cases are missed because we have no definite point on which to make the diagnosis. All the cases reported here to-night and the ones which I have seen have been previously seen by a number of physicians without anyone being able to find out what was the matter with them.

There is one point in the diagnosis which has not been brought up and which was quite definite in two of my cases. They had severe incapacitating pain apparently in the kidney which could not be relieved by morphine but which we were always able to relieve with physostigmine. Apparently the physostigmine restored normal peristalsis in the

ureter, facilitated emptying of the kidney pelvis and gave relief when morphine did not. I believe this is quite an important point in making a diagnosis.

It seems to me that the greatest difficulty is in actually carrying out the operation satisfactorily. You get in there and instead of finding one artery you find several and it is extremely difficult to strip off the nerves completely. In none of my cases has the denervation been complete. However, one case which I did two and a half years ago is still entirely well. She had been an invalid for over a year with severe renal colic but has now been working regularly for two years. She had some recurrence of pain at the end of nine months which disappeared spontaneously. The second patient had complete relief of pain for five and a half months but since then has had some pain about fifty per cent as severe as previously. The last case has been done only recently but has been relieved of all pain.

My thought is that we should have this condition more in mind as a possible diagnosis and not let these patients go on and on if there is a chance of relieving them by such a simple procedure. It would seem to me better to occasionally perform an unwarranted operation than to refuse such patients the possibility of relief merely because we lack adequate means of confirming the diagnosis.

I wonder in Dr. Hepburn's case if he did not do more or less of a renal sympathectomy when he freed up his kidney and ureter and stripped the capsule off the kidney. It seems that this might have played some part in the relief of pain in this case as it has been my impression that very inadequate sympathectomies may be sufficient to break the vicious circle which causes the pain.

E. L. HUNT, M.D. About the cause of death in Dr. Stones' case it is said that the adrenal can stand a good deal of abuse without causing death. I removed a kidney for chronic suppuration with stones in a young woman and had some difficulties in freeing it and when I brought it out there was a good sized tongue of the adrenal with it but she had absolutely a comfortable postoperative course and is well today. That is not quite analogous but it must have disturbed innervation and secretions and other functions which it had in it.

THOMAS N. HEPBURN, M.D. I quite agree with Dr. Barney that very possibly there may be (and I so stated) some other pathology underlying the situation which initiates these spasms. Those of you who have studied in detail the cases reported know that most of these people have had various abdominal explorations. Dr. Wharton has raised the question as to whether they may not be secondary to some pelvic pathology in women and he discussed that possibility in one of his reports. My own statement is that whatever the primary pathology may be by severing the sympathetic nerve connection to the ureter it could not cause spasm of the ureter.

In regard to Dr. Deming's criteria for denervation, I think these cases are very sensitive to cystoscopy. As a routine I anesthetize all my cystoscopic patients so that I am not able to corroborate his first sign of extreme tenderness. I think we find a great many patients who do not need sympathectomy whose ureter will grasp the catheter as you roll it. This observation alone certainly does not warrant denervation. I think his emptying time is very suggestive and more valuable. The real decision must be based on the frequency, severity and crippling character of the attacks.

As to Dr. Pearson's suggestion that my operation denervates the kidney I confess that I capsulated

morning of the second postoperative day her condition was as stated above. He was called in by a nurse fifteen minutes later. The patient was in a state of shock, simulating acute hemorrhage. She was pallid, cold and clammy. The pulse was weak and thready and its rate had increased to 130, the blood pressure was 90 systolic. Respirations were rapid and shallow, aided by the accessory muscles

PLATE II Case II. Intravenous urography (16 minutes)

PLATE III Case II. Intravenous urograph (one hour) suggesting spasmodic constriction of the uretero-pelvic junction.

Perhaps the most marked feature was an immense distention of the abdomen, which fifteen minutes before had been soft and scaphoid, and peristaltic sounds had disappeared. Stipes, enemas, peristaltin and pituitrin had no effect on the distention. Caffeine and adrenalin produced no rise in blood pressure or improvement in the cardiac condition. Examination of the heart showed no enlargement and

only those murmurs which were present preoperatively. There was transitory improvement following intravenous administration of glucose. About 4 P.M. her temperature dropped to 96°, later there was a slight terminal rise. She had no pain whatsoever and the great abdominal distention apparently caused no distress. When seen at 6:15 p.m. she was conscious, rational and unapprehensive, although she was obviously in extremis, and complained only of feeling weak. She died at 6:30 P.M.

It is to be noted for what it may be worth, that during her fifty-eight hours of postoperative life, she had no recurrence of the right kidney pain.

An autopsy was performed three hours postmortem. No sign of hemorrhage, either in the operative field or intra-abdominally was found. The heart showed no thrombi, emboli or coronary occlusion, a mild chronic rheumatic endocarditis involving the mitral and aortic valves was present. The large bowel showed a patent constriction at the hepatic flexure, above and below which the gut was markedly dilated. The operative field showed a slight fibrinous exudate on the denuded kidney surface, although an encapsulated mass 10 cm. in diameter was found superior and slightly anterior to the upper pole. This was purplish in color, on opening the sac a hemorrhagic exudate escaped in which there were some clots. The mass was found to surround the adrenal gland. Both kidneys appeared grossly and microscopically normal. Microscopic preparations of the right adrenal showed no abnormality, other than an inflammatory reaction at its surface. The brain, and in particular, the region of the diencephalon appeared normal to inspection and on histological examination, except for some areas of vacuolization in the cerebrum. The ventricular and spinal fluids were normal. Sections of the cord showed only some accumulation of small round cells about the central canal.

The hemorrhagic reaction about the adrenal did not sufficiently disturb that gland to be interpreted as the cause of death. The collapse seemed too delayed to attribute to the spinal anesthesia, particularly as the intervening period had been free of any symptom referable to that procedure. The whole picture of the disaster was that of a sudden sympathetic paralysis, apparently involving its central control mechanism. The marked intestinal distention bespoke a sympathetic paralysis. The heart rate, which was never particularly high even at the crisis of the collapse, dropped to 70 as death approached, suggesting that the sympathetic accelerator influence was eliminated and the vagi were in control. This was borne out by the drop in blood pressure.

What the rôle of the reaction about the right adrenal gland may have been is difficult to determine. It is certainly theoretically possible that if it failed to produce adrenalin, such reduction may have so decreased sympathetic tone that the system went to pieces. This might account for the delay in the reaction. It is further suggested by the fact that whereas preoperatively, the intravenous injection of adrenalin had produced a terrific response after the supposed collapse of the sympathetic nervous system, similar injections failed to produce any appreciable effect, i.e., the response was that of a vagotonic, the sympathetic balance having been entirely eliminated. For these reasons it was considered that the patient died of sympathetic system paralysis.

DISCUSSION

J. D. BARVEY, M.D. I am very much interested in Dr. Hepburn's paper and in Dr. Stone's paper. It was not quite clear to me, however, how they were so thoroughly convinced that there was no other lesion in some other part of the body which

case was obtained from the surgeon who operated upon her

Upon arriving at the hospital she was examined. A catheter was passed and four ounces of boric acid solution put into the bladder. This returned and the diagnosis of rupture of bladder was questioned. The surgeon on duty was then sent for, and decided that she had a definite surgical belly and that there was an intra-abdominal hemorrhage and that immediate operation was indicated. A preoperative intravenous of saline solution was given. Spinal anesthesia was used and the abdomen opened. A large amount of free blood was found in the abdominal cavity and pelvis, and after palpation of the uterus and appendages which were apparently normal, the bladder was palpated and a rent in the fundus found which admitted four fingers. The blood was sponged out, the rent in bladder closed with suture and the abdominal incision closed. Just before the completion of the abdominal closure the patient expired on the table.

This case presents several points which I wish to make and which are the entire object of this short report. Dr. Arthur H. Crosbie in reporting a case of rupture of the urinary bladder (*Journal of Urology*, October, 1924), makes three definite points in the treatment of cases of rupture of the bladder. I wish to give those points here and to supplement them with further suggestions relative to these cases.

1 The importance of free suprapubic drainage in all cases, whether extra- or intraperitoneal rupture.

2 That there is no need of flushing out the abdominal cavity in cases of intraperitoneal rupture.

3 That it is not necessary to take time to sew up all the rents or tears in a bladder. Free drainage of the bladder using a one-half inch soft rubber tube. Nature will take care of the healing as the rents are bound to be fairly well approximated.

These general principles announced by Dr. Crosbie I wish to subscribe to and to add the following comments and suggestions regarding diagnosis and treatment.

1 That we may have a spontaneous rupture of the urinary bladder from overdistention which may occur along with some medical or surgical condition or as a postoperative condition.

2 That the urinary bladder may rupture extraperitoneally or intraperitoneally when overdistended, with no history of trauma but simply from overdistention with comparatively little voluntary muscular effort on the part of the patient.

3 In arriving at a diagnosis of rupture of the bladder it is important to have at least sixteen to twenty ounces or more fluid put into the bladder and see how much return we get from this larger amount. A smaller amount of fluid put into a bladder which has a rent in the

fundus is not sufficient to reach the fundus and the rent and the entire small amount may be returned through the catheter. If, however, we put in at least sixteen ounces, enough to well fill the bladder, we will get a definite indication from the amount of return.

4 These cases should have a transfusion at the beginning and during operation.

5 It is unwise to remove the blood from the pelvis and abdominal cavity. If the bladder is clean there is very little probability of infection and if the bladder is not clean, but is an infected bladder, we gain nothing by sponging out or flushing in a case of this type, as we will not lessen the infection which has already taken place.

6 Blood in the abdomen should be left in and not sacrificed as it means a great deal to the welfare of our patient. This is demonstrated very definitely in the profuse bleeding of extrauterine pregnancy or in surgery where we have a great amount of bleeding and in which we can squeeze the blood from the sponges and pads and leave it in the abdomen to act, as we might say, as a definite auto-transfusion. It is surprising how much benefit a patient gets from leaving this blood in and how different the convalescence is from those cases in which this large amount of blood is sponged out and sacrificed.

7 The choice of anesthetics in these cases is important. A general anesthetic or a local novocain block is far preferable in these cases with extreme hemorrhaging and very low blood pressure.

DISCUSSION

C. L. DEMING, M.D. There is one other thing I think which may be done to make a diagnosis in ruptured bladder cases which is the injection of air followed by x-ray. Intraperitoneal rupture will show the air under the diaphragm while an extraperitoneal rupture will disclose the air in the tissues about the pelvis.

B. D. WETHERELL, M.D. Would not intravenous urography show a ruptured bladder? Last month I had the opportunity of seeing a girl of 35 who had a tuberculous bladder and I recovered the acid fast bacilli from the left kidney which was a large

the kidney with that in mind, hoping that I would get a "gun shot" surgical effect, but I certainly did not strip the nerves from the renal artery wall of the renal pedicle, as advocated by Papin. My conviction is that the nephralgia is due to ureteral obstruction. Remember that my kidney became painful when the ureter was obstructed by an extra-ureteral pressure after my denervation operation, thereby proving that the sensory nerves to the kidney were still functioning.

ERIC STONE, M.D. I would like to make one comment on the question of diagnosis. I was surprised in a review of the urological literature to find how little attention had been paid to the very easily obtained medical points that appear in a sympatheticotonic individual. Both the cases I reported were demonstrated to be not only sympatheticotonic as regards that kidney but the entire individual make-up was sympatheticotonic.

SPONTANEOUS INTRAPERITONEAL RUPTURE OF THE URINARY BLADDER*

Report of A Case

BY ARTHUR T. JONES, M.D.†

RUPTURE of the urinary bladder may be divided into two types, intraperitoneal and extraperitoneal. In reviewing the literature we find many cases of rupture of the bladder reported. These cases are due to various causes, such as trauma, especially in these days of frequent automobile accidents, also from instrumentation, from the presence of definite pathology in which the bladder wall is involved, or in which there is erosion into the bladder from inflammation and continuity of tissue, as in diverticulitis, tuberculosis, etc.

The reported cases, however, of spontaneous rupture of the bladder with no pathology, the condition being simply one of an overdistended bladder, are rather rare in the literature. In earlier days most of these cases were in men who had been drinking heavily and were unaware that they had an overdistended bladder but found they were unable to void, or they were brought into the hospital in a decided state of intoxication with symptoms of extravasation of urine. Cabot in his writings speaks of most of the cases being of this type. I think that we hardly realized in those days the actual condition which existed, namely, that it was a definite extraperitoneal rupture of the bladder with extravasation of urine into the surrounding tissues. We were inclined to look upon the extravasation as the real entity, treated that, as of course we should, obtained entrance to the bladder by sound and catheter and in due course of time most of these patients recovered.

Intraperitoneal rupture presents an entirely different picture, however, and the case that I wish to report presents definite symptoms and calls for a definite line of treatment quite different from the case of extraperitoneal rupture. Dr. B. H. Alton of Worcester reported before the New England Surgical Society at Portland, Maine, in 1931 a case of spontaneous intraperitoneal rupture of a tuberculous blad-

der. At that time in discussing his paper I took occasion to mention this case that I had seen and I find that my remarks are reported in the "Transactions of the New England Surgical Society for 1931" in the discussion of Dr. Alton's paper. I think, however, that I may report the case at this time and emphasize the points regarding diagnosis and treatment which I wish to make on this subject.

Patient F. G., aged 32, white, single, female, was seen by me in consultation December 15, 1930.

Previous History. Menstruated November 22nd, regular time. Has been flowing for five days, being ahead of time about ten days. She had been well until three weeks previous to my seeing her. She had been under treatment by her family doctor for a cough and pulmonary condition and ten days previous to my consultation had definite signs of a bronchopneumonia.

Present illness dates from five days ago, since which time the abdomen has been distended. There was a large mass in the lower abdomen, more prominent on the left side. The tumor was elastic and was regarded by her doctor as a possible ovarian cyst. To-day (December 15th), her condition has been improved until this evening when, in raising herself a bit to take her medicine from the nurse, she experienced severe pain and the sensation that something in the abdomen had burst. The patient's condition was extremely bad and it was evident that something unusual had occurred. Her doctor was immediately sent for. Consultation was asked and I saw the patient an hour or two after the occurrence of these symptoms.

Examination showed the patient in bed, a well nourished woman, who appeared to be extremely ill, eyes rather staring, anxious looking and breathing rapidly. The abdomen is distended and tense. There is some dullness over the pubes and about half way to the umbilicus. The large elastic tumor which was previously present had apparently disappeared. Pulse was 100, getting decidedly weaker, and in less than one-half hour was very weak and irregular. Further questioning of the experienced nurse on the case revealed that for the past several days when the patient coughed she could not hold her urine and that there had been more or less dribbling of urine for several days, also that she voided at frequent intervals but only a small amount. A catheter was passed and ten to twelve ounces of bright blood or bloody fluid was obtained. A diagnosis of spontaneous rupture of the bladder was made and the patient was sent to the hospital for immediate operation. The further history of the

THE DIAGNOSIS AND MANAGEMENT OF
OBSTRUCTIVE JAUNDICE*

BY HOWARD M. CLUTE, M.D.† AND NEIL W. SWINTON, M.D.†

THE successful management of obstructive jaundice is primarily related to the early diagnosis of an obstructive lesion in the larger biliary ducts. Here, as in many other surgical conditions, we are so dependent on the recognition of a partial or complete obstruction to the common duct by the physician first in charge of the patient that it is of definite importance to review briefly the significant data from which a diagnosis of such obstruction may be made in any patient. There is an unfortunate tendency among many lay-people and practitioners of medicine, as well, to consider jaundice which is not accompanied by alarming symptoms, as a more or less innocuous symptom for which no active investigation is indicated. The policy of postponing active investigation for weeks, or even months in jaundiced patients is directly responsible for the frequency of complications and fatal results in those jaundiced patients who must come to surgery. It is our belief that patients with jaundice should be considered as having an obstruction to their common duct, until other cause for the jaundice is found, that jaundice lasting more than a few days should be carefully investigated and its cause determined, and that jaundice proved to be obstructive in origin should, in general, be submitted to active surgical measures for its relief.

We wish to review at this time the diagnostic measures which are of value to us in active clinical work in the diagnosis of obstructive jaundice. First, it is well known that obstructive jaundice almost always arises from one of three conditions, stone in the larger bile ducts, strictures of the larger bile ducts or malignancies involving the bile ducts. With this situation in mind, therefore, one very commonly can determine from the clinical history alone whether a patient with common duct obstruction is suffering from stones, stricture or cancer.

The clinical history of common duct stones is well known. In the first place the history is that of a recurrent disease and not of a progressive process. Attacks of pain are the prominent features. In the typical case these attacks of terrific pain are followed by fleeting jaun-

dice. Secondary digestive disturbances consist mainly of distress and pressure in the epigastrium and most particularly of gaseous distention and eructation.

The typical history of stricture of the common duct differs materially from that of stones. Usually the patient has had a previous operation upon the biliary tract, commonly a cholecystectomy. If inquiry is made into the post-operative course it will be found that for the first few days after the operation all went well. Soon, however, marked bile drainage was noted from the drainage tract and this drainage of bile persisted for a matter of six to eight or more weeks. Gradually the external biliary drainage ceased and jaundice, either complete or partial and intermittent, was noted. Since the date of the operation, in many instances, jaundice has been complete and constant. In other cases in which the stricture is less complete attacks of fever, chills with transient jaundice and more or less epigastric distress and discomfort have been noted. In strictures of the common duct attacks of serious pain are rare in the clinical history.

In malignancy of the pancreas involving the common duct or one of the larger bile ducts, the typical clinical history is well known. Classically it is marked by the development of a painless jaundice accompanied by well-marked weight loss. Occasionally, however, malignancy of the pancreas with increasing jaundice may be accompanied by severe attacks of pain, since at times gall stones are present in the gall bladder to cause the pain in malignancy of the pancreas.

On clinical examination in obstructive jaundice there are relatively few findings which by themselves alone will determine the diagnosis. Thus, local tenderness and local spasm following attacks of upper right abdominal pain are significant of pathology in the biliary system. It has been our experience that local tenderness is commonly present after attacks of common duct colic if the gall bladder is present, but if common duct colic occurs after the gall bladder has been removed, such local symptoms are not prominent.

When the obstruction to the common duct is complete and lies below the junction of the cystic and common hepatic bile duct, as in cancer of the head of the pancreas, dilation of the biliary tree, including the gall bladder, is present. A dilated gall bladder has been palpable, however, in only 33 1/3 per cent of our recent cases of

The Lahey Clinic, Boston, Mass.
Read at the Annual Meeting of the Vermont State Medical Society at Barre, October 6, 1933.

one, but she had no right kidney at all. She died about two months later.

RICHARD CHUTE, M.D. Would there be any objection to injecting sodium iodid in making the diagnosis or would that be too irritating?

A. T. JONES, M.D. It would seem to me that it would be. I should think that all that really would be necessary would be some plain solution, sterile water or saline or boric acid, and see if you get a return. The doctor on my left has suggested the injection of lipiodol. It would take a considerable amount of that and it would require x-ray plates, whereas we can come to the conclusion of ruptured bladder if we put in a small amount and get it all back. The error in these cases was in putting in a large amount.

In regard to the question Dr. Wetherell asked I can hardly comprehend how a skilgram would give a picture of the bladder sufficiently good to arrive at the conclusion of a rupture of the bladder.

C. J. E. KICKHAM, M.D. Very little has been said with regard to the use of cystoscopy in the diagnosis of rupture of the bladder. During the last several years at the Carney Hospital we have diagnosed three cases of ruptured bladder by means of cystoscopy. In each of these cases the rent was visualized. In one of these cases we just cystoscoped the patient in bed, without any upset on the part of the patient, and absolutely no trauma. I feel that the cystoscope is useful in the diagnosis of rupture of the bladder.

RIGHT RENAL CALCULUS ASSOCIATED WITH MULTIPLE BILIARY CALCULI*

BY CLINTON N. PETERS, M.D.†

MRS. H., aged 36 February 5, 1931

Complaint Pain in the upper right quadrant accompanied by nausea and vomiting.

X-ray shows shadow 3 mm. lying between eleventh rib and transverse process second lumbar vertebra.

Cystoscopic Examination on February 5

Plain Plate Catheters in position show shadow triangular in area one-half inch below end of right catheter. **Diagnosis** Right renal calculus.

Pyelogram shows normal left kidney. Right side pyelogram includes shadow in renal pelvis. **Diagnosis** Calculus right renal pelvis.

Physical Examination Essentially negative except some tenderness in upper right quadrant. This is more marked over the anterior surface than on the vertebral angle. Advise dye test for gall bladder.

Graham-Cole Test Kerasol by mouth shows malfunctioning gall bladder with shadow of calculus outside gall bladder which is faintly mottled. In travenous Graham-Cole test gall bladder is seen below twelfth rib. This is mottled with negative shadows consistent with biliary calculi. The positive shadow representing renal calculus is seen through the other shadows. One hour after fatty meal there is no change. **Diagnosis** Malfunctioning gall bladder with multiple calculi.

Hospital History March 9, 1931—Moderate sized gall bladder full of calculi removed. Convalescence uneventful. Left hospital March 26. On May 7, 1932, readmitted with same symptoms. On May 9, cystoscopic examination. X-ray plate showed renal calculus to be in relatively same position. May 11, through right oblique incision the right kidney pelvis was opened and calculus removed. Convalescence uneventful and patient left the hospital on June 3, 1932.

Follow-Up Patient seen on September 5 and December 20 in good health and without symptoms.

*Presented before the New England Branch of the American Urological Association February 15, 1934.

A REPORT OF FOUR UNUSUAL CASES*

BY W. G. TOWNSEND, M.D.†

IN the first place, I feel that I owe you all an apology because there is nothing instructive or highly scientific in any of these pictures. To me they are just interesting but after all, if it were not for the interesting and bizarre cases, it would not be much of a life we lead.

The first picture is of a man of twenty-five with typical left renal colic. Intravenous urography after cystoscopic examination was unsatisfactory, showed a normal left kidney and a hypoplastic right kidney. To me the interesting thing was that his pain was on the left side and had nothing to do with the hypoplastic right kidney.

The next picture is of a woman of forty-three with staphylococcus aureus infection of her bladder. A routine check-up revealed congenital solitary right kidney. We could find no ureteral orifice and no dye came through, and again an intravenous urography showed nothing in her left side at all. She is well and healthy.

The third is a woman in her fifth pregnancy. She had right renal colic. She has a stone here and here. We got this plate, then she happened to sit up or turn around and the next plate shows the stone in the transverse position. The stone in the pelvis of the kidney turned on its long axis.

And, just to prove that all kidney stones in Vermont are not small, I have this one which weighed 398 grams.

Presented before the New England Branch of the American Urological Association February 15, 1934.

†Townsend, W. G.—Associate Professor of Urology, University of Vermont College of Medicine. For record and address of author see *This Week's Issue*, page 1237.

X-ray evidence in common duct obstruction is usually of no practical value. Plain x-ray plates of the abdomen, however, which show gall stones are of course very significant in jaundice. We have avoided giving gall bladder dye to patients with jaundice because we feared the possible reactions that might ensue. We are familiar with the fact that certain men have employed this procedure yet we feel that in the presence of jaundice the information which gall bladder dye may give is not worth the added risk of its administration.

Duodenal drainage for diagnostic purposes has been perhaps the most satisfactory and dependable laboratory test for determining the cause of jaundice that we have used. Duodenal drainage can be used with relatively little disturbance in even the most seriously jaundiced patients. Duodenal drainage tells us first whether the common duct is patent, and whether bile is entering the duodenum. If the obstruction to the common duct is complete, occasionally the gastroenterologist will tell us that it is due to malignancy involving the ampulla as is shown by the recovery of blood and epithelial structures from the duodenum. If duodenal drainage returns bile from the duodenum we know, first, that the common duct is not completely obstructed and secondly, by the microscopic examination of the bile further important data are obtained. Thus the presence of calcium bilirubin crystals is diagnostic of calculus formation in the gall bladder or main bile ducts. The presence of pus and epithelial debris is significant of an infectious process. Failure to obtain gall bladder bile on stimulation indicates absence of gall bladder function. In thirty-one cases in whom duodenal drainage was carried out by Dr. Wilkinson, in the Gastroenterological Department in the Clinic, thirty correct diagnoses have been established at operation and one error has been noted. We recommend this procedure particularly for use in jaundiced patients and in those patients in whom the usual gastroenterological studies have been uncertain.

In the last two years we have used the galactose tolerance test to determine whether the jaundice was infectious or hemolytic or obstructive. At best it seems to us that this test is but confirmatory of other findings and by itself alone could not be depended upon to settle the diagnosis.

Assuming that, from the clinical history and examination and from the laboratory studies, obstructive jaundice is present, either from stones, stricture or cancer, surgical intervention is indicated save in those cases long neglected and obviously hopeless, who would certainly not withstand any operative procedure. The surgery of obstructive jaundice has always been considered extremely hazardous. These patients

do not stand operation well, because kidney damage is sometimes present, liver damage is constantly present, and because many of them have a tendency to bleed after operation. Only as we recognize these complicating factors, that may possibly arise in these patients, and as we take special precautions to prevent them, can we hope to operate successfully to remove the cause of the obstruction to the common duct. In estimating the operative risk in these patients we must consider in each one certain significant data. Thus studies of the non-protein nitrogen of the blood and of the phenolsulphonephthalein excretion in the urine give us an immediate index of the degree of kidney damage which has arisen from the concentration of the bile salt in the blood and in the urine and from the diminished fluid intake which is usually present.

The degree of liver damage cannot as yet be satisfactorily measured by any single test available for clinical use. In clinical practice liver damage however, is a very real condition though it may not be measured in actual figures. We may estimate the probable degree of liver damage by the history of the length of the jaundice. Obstructive jaundice going on for months invariably is associated with serious liver damage. A high secretion of urobilinogen in the urine is direct evidence of the inability of the liver to metabolize urobilin in the blood stream into bilirubin. A constantly high bilirubin is further evidence of probable liver damage.

The tendency to bleed in these patients cannot be accurately estimated by any laboratory test, which has, as yet, been devised. The bleeding time and the coagulation time are not reliable for this purpose. The clotting index is not practical. A rapid sedimentation rate in which the red cells in the blood settle more than thirty millimeters in thirty minutes has been said, by Linton and others, to indicate a probable tendency to bleed after operation. In our experience this test is by no means accurate, yet it is the only test with which we have had experience, which is highly suggestive and, therefore, of distinct clinical value in prognosticating the tendency of patients to bleed in obstructive jaundice.

It is fortunate that the three major complications, which may occur after operation in obstructive jaundice, can be largely controlled and prevented by the same therapeutic measure, namely, the administration of large amounts of fluid and of carbohydrate, particularly in the form of glucose. The high fluid intake dilutes the toxic material in the blood stream and increases kidney secretion thus, diminishing kidney damage. The high carbohydrate intake, which is given as glucose intravenously and subpectorally and as carbohydrate food by mouth is of great importance in restoring the glycogen reserve in the liver and so limiting liver destruc-

malignancy involving the biliary tract, since in many cases the malignant process obstructs the biliary tract proximal to the cystic duct or invades the cystic duct itself and so prevents dilatation of the gall bladder

Jaundice is, of course, the one outstanding clinical finding which at once points to a possible obstruction of the common duct. Because of this fact and because the changes in physiology, which accompany jaundice, may make these patients serious surgical problems, it is important that this clinical finding be considered with especial care

It has been taught that common duct stones were usually associated with jaundice either transient or constant in type. In a previous analysis of our¹ cases of common duct stones in seventy-two patients, it was found that thirty per cent of the patients had no jaundice at the time of their operation and had no history of jaundice in the past. Judd² has reported that twenty-five per cent of the common duct stones seen in the Mayo Clinic gave no history of jaundice in the past and had no jaundice at the time of operation. For the purposes of this particular study we have reviewed all the cases of biliary tract disease seen at the Lahey Clinic in 1931 and 1932. In these two years there were forty-six cases of common duct stones, of whom sixty-three per cent had a history of jaundice at the time of operation. Thirty-seven per cent, however, of these forty-six cases of proved common duct stones had no jaundice at the time of operation and had no history of jaundice in their previous illness. This demonstrates, we believe, once again very emphatically that the presence or absence of jaundice cannot be considered a positive criterion for the presence of common duct stones.

In strictures of the common duct, jaundice has been present either in the history or at the time of examination in every case that we have ever seen. In the six cases treated in the past two years all had jaundice at the time of their admission to the Clinic.

Jaundice is a common symptom in malignancy involving the common duct, but it is not necessarily an early symptom. Thus in one patient whom we had personally followed for some months with vague epigastric disturbances, jaundice was not present until eight days before operation. At operation, however, malignancy of the pancreas was found which by slowly increasing pressure upon the common duct had made the common duct dilate to nearly three-fourths of an inch in diameter. Only when the obstruction to the duct became complete, however, did jaundice actually appear in this case. In the cases of malignancy involving the bile ducts seen in the past two years, jaundice was present in fifty per cent and absent in fifty per cent.

The laboratory data, on which we must de-

pend for determining the actual presence of obstruction to the common duct as a cause of the jaundice, are largely designed to estimate the origin and degree of the jaundice. It has been our experience that the very simplest laboratory examinations of testing the urine for bile and observing the color of the stools not infrequently are quite sufficient to settle the diagnosis if they are repeatedly performed and correctly interpreted. In clinical practice bile in the urine and gray-colored stools mean obstruction of the common bile duct. We have occasionally been quite surprised to find showers of bile, so to speak, in the urine in patients who had attacks of excruciating upper abdominal pain with no visible jaundice. To observe this bile, however, the urine must be tested repeatedly during the hours and days following the attacks of pain. Furthermore, in these cases such a shower of bile in the urine is occasionally accompanied by a definitely clay-colored stool, which confirms the diagnosis. When bile is present in the urine and the stools are persistently brown in color, however, we know at once that if the jaundice is obstructive in type the obstruction is not complete and we recognize that of course the jaundice may be of infectious or hemolytic origin under these circumstances.

Studies of the urobilinogen in the urine are readily performed and give helpful information in two ways. First, the absence of urobilinogen from the urine means complete obstruction of the common bile duct. Secondly, large amounts of urobilinogen show well-marked liver damage. A normal urine urobilinogen shows the absence of complete common duct obstruction and the presence of good liver function.

Various methods of precision are at hand for the estimation from blood examination of the degree of retention of the bile pigments. Of these methods, we prefer in our clinical work to use the bilirubin test, which is a relatively simple test giving us the precise figure or the amount of bile pigment in the blood stream. One may consider that the normal individual will have from one tenth of a milligram per 100 cc of blood to five tenths. When the bilirubin is more than five tenths, jaundice is latent and when the bilirubin is one and over the jaundice is usually visible. Here again, repeated studies of the bilirubin are of greater value than single tests. After a serious attack of abdominal pain the bilirubin may be elevated for a day or so with no visible jaundice. In patients who have obvious jaundice, daily studies of the bilirubin determine whether the jaundice is stationary or increasing or decreasing in severity. Furthermore bilirubin estimations give us inferential evidence of the presence or absence of liver damage. Thus, we may infer that when the bilirubin is constantly elevated to a high figure over many days that liver damage is doubtless present.

sedimentation rate is followed very closely and when it is rising we are at once suspicious of the possibility of hemorrhage. Pink staining in the biliary drainage, slight oozing about the sutures in the skin of the wound, frank oozing along the drainage tract, oozing from the gums, blood in the urine or stools demand immediate and if need be repeated transfusions. Blood donors must be matched and grouped before operation and be readily available so that they may be used at once when the first signs of oozing occur. It is our custom to have several donors available for each patient with obstructive jaundice before operation is undertaken.

In patients having obstructive jaundice due to a benign lesion in whom complete recovery is possible, if hemorrhage does occur, there is almost no limit to the lengths which we must go to control bleeding. Thus in a recent serious case twelve blood transfusions were given of which eight were given within three days during the period of the most serious and extreme bleeding. Her recovery was complete and satisfactory. When hemorrhage occurs from obstructive jaundice due to a hopeless stricture within the liver substance not amenable to surgery, or to some hopeless malignancy such extreme measures as used in the case just mentioned, are not necessarily indicated.

Since we have adopted this method of management in obstructive jaundice, our results have been increasingly satisfactory. Reviewing the cases seen and cared for in 1931 and 1932 we find that there have been thirteen patients with definite and serious obstructive jaundice due to common duct stones. All of these were operated upon and four of these patients had bleeding postoperatively. No patients in the group died from hemorrhage. One of the thirteen patients died eight weeks after operation from multiple liver abscesses.

In the same interval there were six cases of stricture of the common duct. Five of these were sequels of previous operations upon the biliary tract done elsewhere and one resulted from an automobile accident which ruptured the common duct. Three of these patients died from hemorrhage and liver failure. Their strictures were within the liver substance and so could not be repaired surgically. All had been jaundiced for months or years before admission. Three of these stricture patients made recoveries, since their strictures were so situated that they could be repaired. One of these three had serious hemorrhages after operation but was carried through safely by repeated transfusions, six in number.

In 1931 and 1932 we operated upon fifteen patients with malignancy involving the biliary tract. Of these patients twelve recovered from the operation and left the hospital and three died from inanition. Three had definite bleeding postoperatively controlled by blood transfusions and none died of hemorrhage.

It is to be noted that in the thirty-four cases of obstructive jaundice operated in the Clinic in the last two years, hemorrhage has occurred ten times and was a fatal factor in three hopeless stricture cases. Fatal hemorrhage did not occur in any benign obstruction of the biliary system.

In summary. The successful management of obstructive jaundice depends upon

- 1 The early diagnosis of obstructive jaundice. We feel that jaundice in adults should be considered of the obstructive type until proved otherwise and any case presenting itself with jaundice should have the benefit of immediate study to differentiate it from the infectious and hemolytic forms.
- 2 There are in clinical practice only three main causes of obstructive jaundice. Common duct stones, strictures of the ducts, and malignancies involving the ducts.
- 3 The diagnosis of obstructive jaundice can commonly be made from the history, presence of bile in the urine and the finding of clay-colored stools.
- 4 Certain other laboratory data give us additional information concerning these cases. Absence of urobilin in the urine indicates complete obstruction of the ducts. Large amounts of urobilin indicate liver damage. Repeated bilirubin determinations indicate the course of the jaundice and some inference of the extent of liver damage. Duodenal drainage is one of our most accurate procedures in determining the presence of common duct obstruction and aids in the differential diagnosis of its cause.
- 5 The diagnosis of obstructive jaundice being established, the patient should be considered a surgical problem and immediate steps taken to prepare him for operation.
- 6 The adequate utilization of fluids, glucose, saline and whole blood transfusions will prepare these patients for operation. Operation should be undertaken when no further improvement in the patient is noted with the use of the above measures.
- 7 Following operation, of the three usual complications, bleeding is our most serious and feared complication. Bleeding following operation is best treated by whole blood transfusions.
- 8 In the past two years, in thirty-four cases of obstructive jaundice, bleeding occurred following operation ten times. Death occurred from hemorrhage in three hopeless stricture cases. No death from hemorrhage occurred in any benign obstructive lesion of the common duct.

tion and helping regenerate liver lobules already seriously damaged by long obstruction. Not only should a diet high in carbohydrates be given these patients, but as has been recently shown by Mann, protein should be strictly omitted from their diet.

The administration of fluid, and particularly of glucose, is the best preventive measure at our command for diminishing the tendency to bleed after operation. It is the experience of Ravdin, Linton and others, as well as ours, that this measure alone is adequate to control the hemorrhagic tendency in most patients with obstructive jaundice. When, in spite of this measure, hemorrhage occurs it can, in most cases, be controlled by blood transfusions. The use of calcium chloride intravenously or calcium lactate by mouth, or both, in these patients has been an accepted clinical procedure for the prevention of postoperative bleeding. There are some who believe that calcium neither prevents hemorrhage nor stops it once it occurs, while others find it is of value. It is our present belief from our clinical experience that the routine use of calcium is not indicated. If, however, postoperative oozing occurs in spite of adequate fluid and glucose administration, and in spite of blood transfusions, we feel that calcium should be added at once to our methods of treatment since it is the only other known method which may result in checking postoperative bleeding.

It is desirable to relate the actual procedure that we undertake when a seriously jaundiced patient with common duct obstruction is admitted to the hospital. Our first object is to obtain blood for the estimation of the bilirubin, non-protein nitrogen and sedimentation rate and to begin at once the administration of fluid and glucose. Constant venoclysis has proved, in our experience, to be the most satisfactory method by which these objectives may be obtained. On admission then, a cannula is at once inserted in a vein, which has been opened and made ready under local anesthesia, and from this cannula sufficient blood is taken for the tests desired. Venoclysis with salt solution and glucose alternating with distilled water and glucose, so that too much chloride will not be administered, is at once established. By this method three to five thousand cubic centimeters of fluid and one hundred to two hundred grams of glucose or more can be given in each twenty-four hours. The patient is not disturbed. Venoclysis once established in a vein may go without further manipulation for five to eight days. During this same period the patient is given fluids freely by mouth as he may take them and carbohydrate diet, consisting of oatmeal with sugar and cream, milk, custard, fruit juices and ginger ale, et cetera.

In order that we may follow the course of the patient, as shown by the laboratory examinations, and in order that we may note the fluid

intake and output very clearly, we have devised a jaundice chart, which has been of definite clinical value in these patients.

The decision as to when operation should be undertaken and how long the preoperative treatment, with fluids and glucose, should continue is frequently difficult. In seriously jaundiced patients five days of fluid and glucose before operation is usually the least time that should be consumed. In certain cases, who are stuporous or delirious and in whom evidences of kidney failure are marked, seven and eight days may be necessary. In other patients, however, in whom it is obvious that complete obstruction to the common duct is present, and in whom the general condition is satisfactory, operation may be done on the fifth or sixth day of treatment. In general, when doubt exists as to the patient's ability to withstand surgery, venoclysis should be continued for a longer time and preparation should be continued up to eight, ten or even twelve days before operation.

The management of these patients at the time of operation is a technical problem on which we wish to make but one or two general remarks. The first consideration in the operation is the return of the bile stream to the intestinal canal. Occasionally external biliary drainage without returning bile to the intestine is the only procedure possible but whenever it is possible the return of the bile to the intestine is most essential. The presence of the bile in the intestinal canal has a most beneficial effect in obstructive jaundice. The second consideration in the surgery of obstructive jaundice is the permanent relief of the obstruction by the removal of the obstructing stone, the repair of the stricture, or the short-circuiting of the bile tract around the obstructing cancer. Occasionally it is necessary to carry out these procedures in a short time with as little intra abdominal manipulation as possible and with as little hemorrhage and shock as possible. The anesthesia, as is generally known, should bring no added burden to liver and kidney, thus, ethylene oxygen administered by intratracheal catheter and local anesthesia in the operative field are the ideal procedures. Spinal anesthesia, save in the exceptionally good risk, may be distinctly dangerous in serious obstructive jaundice.

Following operation the first seven days are the days in which the major complications most commonly occur. Hemorrhage is the particular danger which must be watched for and controlled. In patients well prepared before operation, postoperative kidney failure and liver failure have not been serious factors in our recent experience. The prevention of postoperative hemorrhage should start with blood transfusion in the seriously jaundiced patient at the time of operation. Glucose and salt solution are constantly administered by venoclysis for the first five to seven days after operation. The

been on a diet of cow's milk and which, when first seen, had a hemoglobin percentage of 23 and erythrocyte count of 2,220,000. After regulation of the diet, a small blood transfusion and administration of copper and iron, the general condition rapidly improved and the blood count returned to normal.

Following Dr Johnson was Dr T E Hays, Instructor in Physiotherapy, who discussed the prevention and correction of deformities of arthritis. Dr Hays illustrated, with x-ray films and with patients the more usual types of deformities that commonly result from atrophic and hypertrophic arthritis and the means employed to avoid them as the disease advances or to correct them after they have developed. He particularly warned against the flexion deformity of the dorsal spine which cramps the chest and causes serious interference with the proper function of the heart, lungs and abdominal organs. Dr Hays demonstrated several devices which are of value in preventing or treating deformities, and discussed the use of such measures as heat, massage, rest and exercise.

Dr W G Townsend, Professor of Urology, next spoke on "Transurethral Prostatic Resection," briefly describing the operation, the indications for its use and the results to be expected following it. He stated that this type of operation was of great value in patients who have obstruction resulting from median bar or unilateral enlargement of a lateral lobe in patients whose general condition prohibited the more serious complete prostatectomy, or to secure better drainage in patients with carcinoma of the prostate. Dr Townsend's discussion was illustrated with lantern slides and a demonstration of the instruments used.

'Flat Feet' was the topic discussed by Dr R. L. Maynard of the Department of Orthopedic Surgery. Dr Maynard first described the anatomy of the foot and ankle, with special reference to the structure of the arches and the line of weight bearing. He next explained the anatomical and physiological changes resulting from faulty weight bearing strain, arthritis and paralysis with the symptoms and signs of each. The differences between metatarsal and longitudinal arch weakness were discussed together with the alterations in line of weight bearing which are brought about by each. In describing various modes of treatment, Dr Maynard explained the proper ways of applying adhesive straps, and of making plaster impressions of the feet, from which metal plates may be made and discussed the features which good fitting shoes should have to aid in correction of the deformity. In closing Dr Maynard demonstrated how a foot should be strapped with adhesive plaster.

At this time the assembly divided into various groups which attended the following demonstrations:

'Preparation of Formulae for Infant Feeding' under the direction of Dr C K. Johnson.

'Physiotherapy,' under the direction of Dr T E. Hays.

The Stethophone, by Dr H. E. Upton.

"Transurethral Prostatic Resection," by Dr W G Townsend.

"Mastoids," by Dr M C Twitchell.

"Plaster Casts of the Feet," by Dr R. L. Maynard.

Opportunity was afforded for general discussion of problems relating to the subjects under consideration. The meeting adjourned for luncheon at 1 P M.

The Friday afternoon session opened at two o'clock with a discussion by Drs P E McSweeney and E D McSweeney, of the Gynecology Department, of the commoner tumors of the female generative tract, and the properties and modes of application of radium. Dr P E McSweeney demonstrated gross pathological specimens of tumors, and explained briefly the symptomatology and treatment for each. He also exhibited a patient with a complete inversion of the uterus headed by a large submucous fibromyoma attached to the fundus, and described the technic of the operation which was proposed to correct this condition. Dr E D McSweeney gave a short résumé of the discovery and characteristic features of radium. He demonstrated radium needles and the different types of applicators which may be used. He also discussed the types of conditions which were particularly suited to radium therapy, the methods of application and the dosage employed.

The Department of Ophthalmology, as represented by Drs K C McMahon and A. L. Larner, next conducted a clinical demonstration on the non-surgical treatment of strabismus. Dr McMahon, after explaining the necessity for early correction of squint, outlined the steps for adequate treatment which include visual training of the affected eye, proper refraction, using drops, fusion training, and general constitutional measures for building up the child's health. Dr Larner explained the optical principles involved in the development and subsequent correction of strabismus, illustrating his remarks with blackboard drawings. Drs McMahon and Larner closed by showing about a dozen children who were receiving non-surgical treatment for strabismus.

The Department of Surgery was represented by three speakers: Dr G M Sabin, Dr W T Rees and Dr B D Adams.

Skeletal Traction was the subject of Dr Sabin's discussion. A fracture-bed, upon which a skeleton was placed, was wheeled into the amphitheatre and the various appliances used to give skeletal traction were exhibited before the gathering. The Kirschner wire and apparatus were used in demonstrating the reduction of certain fractures of the femora and tibiae. Following this, x-ray films of several fracture cases were shown to illustrate the value of skeletal traction, especially in badly comminuted fractures of the tibia and femur.

Dr Rees described the use of one per cent aqueous solution of gentian violet in the treatment of extensive cutaneous burns. The advantages of gentian

MISCELLANY

THE CLINICAL MEETING OF THE VERMONT STATE MEDICAL SOCIETY

MARY FLETCHER HOSPITAL, BURLINGTON
MAY 4 AND 5, 1934

For some years the officers of the Society have considered the wisdom of holding a mid-year meeting of the Society, conducted along entirely different lines from those of the regular State Meeting, i.e., clinical demonstrations instead of the reading of papers, and for the first time in the history of the Vermont State Society a clinical meeting was held in Burlington on May 4 and 5. It was an experiment and there was much speculation beforehand as to the response regarding the attendance in numbers and also regarding the reception of the program. The registration of 146 men was larger than the average registration at the Annual State Meeting and the demonstrations were received with pronounced expressions of approval or almost enthusiasm, and the writer believes that the holding of such meetings by State Societies is a most valuable function of the organization, in the smaller States to be held in connection with the leading clinical center, and in the larger States perhaps being held as sectional meetings. The program is a bit too ambitious for a County Society unless it is quite large.

There is no doubt but that this mid-year Clinical Meeting will be adopted as a permanent part of the activities of the Vermont Society.

The exercises as outlined in the program are detailed below.

At the meeting of the Vermont State Medical Society, held in Barre last October, it was voted to hold a mid-winter meeting in Burlington with the cooperation of the College of Medicine of the University of Vermont. However, as it later seemed that many physicians in the state would be hindered by weather conditions, from attending a two-day session in February, the Executive Committee of the State Society decided to postpone it until early May.

On Friday, May 4, and Saturday, May 5, a clinical meeting of the Vermont State Medical Society was held at the Mary Fletcher Hospital, Burlington, Vermont. The program was conducted by the faculty of the University of Vermont College of Medicine, with C. H. Beecher, M.D., Professor of Medicine acting as presiding officer. The other members of the committee in charge were Dr. E. H. Butties and Dr. Lyman Allen and, ex officio, Dr. T. S. Brown, Superintendent of the Mary Fletcher Hospital, and Dr. J. N. Jenne, Dean of the College of Medicine. One hundred and forty-six physicians attended the sessions.

The program consisted entirely of clinical demonstrations and discussions, no formal papers were presented. Most of the sessions were held in the surgical amphitheatre of the hospital, group discus-

sions of various subjects were held in various other parts of the hospital and a few reels of medical motion pictures were shown in the auditorium of the Fleming Museum. Through the courtesy of the Mary Fletcher Hospital, visiting physicians were tendered a complimentary luncheon on Friday noon, in the main dining room of the hospital. On Friday evening an informal dinner was served in the ball room of the Ethan Allen Club, after which the guests enjoyed the privileges of the club. Music was furnished during the dinner by the University of Vermont male quartet.

At the close of the meeting Dr. J. H. Woodruff, of Barre, President of the Vermont State Medical Society, extended the thanks of the Society to the committee, the officers of the Mary Fletcher Hospital and the Medical College. Dean Jenne announced that the College of Medicine would sponsor a similar clinical meeting next year.

In the exhibit hall were several interesting displays of x-ray films and photographs of the cases discussed at the meeting, as well as films and gross specimens of various types of heart lesions. These were prepared and presented by the Department of Pathology. The Department of Anatomy exhibited a number of dried skulls and serial sections of the head to demonstrate the anatomy of the mastoid cells and their relation to the adjacent structures.

Dr. C. A. Newhall of the Dermatology Department, opened the program on Friday morning by presenting four cases, one of eczema, another of psoriasis, a third of scabies, and a fourth of alopecia areata. He outlined the diagnostic features of each case and gave indications and suggestions for treatment. In his discussion of eczema Dr. Newhall demonstrated, by the use of diagrams, the stages through which the disease may pass. He also recommended the use of the so-called "patch test" in cases where external irritants are thought to be etiological factors. At the close of his discussion, printed copies of several standard formulae of ointments for application in eczema, psoriasis and scabies were given to the guest physicians.

The next feature on the program was conducted by Dr. C. K. Johnson, Professor of Pediatrics, who presented several feeding cases. The first infant shown was one which was just recovering from a well-developed rickets, as indicated by frontal bosses, moderate rachitic rosary, a distended tympanic abdomen and typical x-ray changes in the lower ends of the ulna, radius and femur. The child, which had been on a diet of cow's milk exclusively until he was about eight months old, was given cow's milk with lactic acid cereal, egg yolk and vegetables. Vitamin D, cod liver oil, and ultraviolet radiation were administered. The infant was shown at the age of ten and a half months, at which time the general improvement was quite marked, and the x-ray examination showed complete regression of the bone changes. The second case was one of nutritional anemia in a child, sixteen months old, which had

been on a diet of cow's milk and which, when first seen, had a hemoglobin percentage of 23 and erythrocyte count of 2,220,000. After regulation of the diet, a small blood transfusion and administration of copper and iron the general condition rapidly improved, and the blood count returned to normal.

Following Dr. Johnson was Dr. T. E. Hays, Instructor in Physiotherapy, who discussed the prevention and correction of deformities of arthritis. Dr. Hays illustrated, with x-ray films and with patients, the more usual types of deformities that commonly result from atrophic and hypertrophic arthritis and the means employed to avoid them as the disease advances, or to correct them after they have developed. He particularly warned against the flexion deformity of the dorsal spine which cramps the chest and causes serious interference with the proper function of the heart, lungs and abdominal organs. Dr. Hays demonstrated several devices which are of value in preventing or treating deformities, and discussed the use of such measures as heat, massage, rest and exercise.

Dr. W. G. Townsend, Professor of Urology, next spoke on "Transurethral Prostatic Resection," briefly describing the operation, the indications for its use and the results to be expected following it. He stated that this type of operation was of great value in patients who have obstruction resulting from median bar or unilateral enlargement of a lateral lobe in patients whose general condition prohibited the more serious complete prostatectomy or to secure better drainage in patients with carcinoma of the prostate. Dr. Townsend's discussion was illustrated with lantern slides and a demonstration of the instruments used.

Flat Feet was the topic discussed by Dr. R. L. Maynard of the Department of Orthopedic Surgery. Dr. Maynard first described the anatomy of the foot and ankle with special reference to the structure of the arches and the line of weight bearing. He next explained the anatomical and physiological changes resulting from faulty weight bearing, strain, arthritis and paralysis, with the symptoms and signs of each. The differences between metatarsal and longitudinal arch weakness were discussed together with the alterations in line of weight bearing which are brought about by each. In describing various modes of treatment, Dr. Maynard explained the proper ways of applying adhesive straps and of making plaster impressions of the feet from which metal plates may be made, and discussed the features which good fitting shoes should have to aid in correction of the deformity. In closing, Dr. Maynard demonstrated how a foot should be strapped with adhesive plaster.

At this time the assembly divided into various groups which attended the following demonstrations:

Preparation of Formulae for Infant Feeding, under the direction of Dr. C. K. Johnson.

Physiotherapy, under the direction of Dr. T. E. Hays.

The Stethophone by Dr. H. E. Upton.

"Transurethral Prostatic Resection," by Dr. W. G. Townsend.

"Mastoids," by Dr. M. C. Twitchell.

"Plaster Casts of the Feet," by Dr. R. L. Maynard.

Opportunity was afforded for general discussion of problems relating to the subjects under consideration. The meeting adjourned for luncheon at 1 P. M.

The Friday afternoon session opened at two o'clock with a discussion by Drs. P. E. McSweeney and E. D. McSweeney, of the Gynecology Department, of the commoner tumors of the female generative tract, and the properties and modes of application of radium. Dr. P. E. McSweeney demonstrated gross pathological specimens of tumors, and explained briefly the symptomatology and treatment for each. He also exhibited a patient with a complete inversion of the uterus headed by a large submucous fibromyoma attached to the fundus, and described the technic of the operation which was proposed to correct this condition. Dr. E. D. McSweeney gave a short résumé of the discovery and characteristic features of radium. He demonstrated radium needles and the different types of applicators which may be used. He also discussed the types of conditions which were particularly suited to radium therapy, the methods of application and the dosage employed.

The Department of Ophthalmology, as represented by Drs. K. C. McMahon and A. L. Larnier, next conducted a clinical demonstration on the non-surgical treatment of strabismus. Dr. McMahon, after explaining the necessity for early correction of squint, outlined the steps for adequate treatment which include visual training of the affected eye, proper refraction, using drops, fusion training and general constitutional measures for building up the child's health. Dr. Larnier explained the optical principles involved in the development and subsequent correction of strabismus, illustrating his remarks with blackboard drawings. Drs. McMahon and Larnier closed by showing about a dozen children who were receiving non-surgical treatment for strabismus.

The Department of Surgery was represented by three speakers: Dr. G. M. Sabin, Dr. W. T. Rees and Dr. B. D. Adams.

"Skeletal Traction" was the subject of Dr. Sabin's discussion. A fracture-bed, upon which a skeleton was placed, was wheeled into the amphitheatre and the various appliances used to give skeletal traction were exhibited before the gathering. The Kirschner wire and apparatus were used in demonstrating the reduction of certain fractures of the femora and tibiae. Following this, x-ray films of several fracture cases were shown to illustrate the value of skeletal traction, especially in badly comminuted fractures of the tibia and femur.

Dr. Rees described the use of one per cent aqueous solution of gentian violet in the treatment of extensive cutaneous burns. The advantages of gentian

violet over tannic acid and other drugs, the technic of application, and the general management of the case were all briefly but comprehensively discussed, and two patients who had received the gentian violet treatment were shown. Both patients had been seen shortly after receiving their burns, which were very extensive, both patients were comfortable and free from pain within a short time after the application of gentian violet, both had been skin grafted and had healed without contractures.

Dr B D Adams presented two cases, one of lung abscess and one of chronic empyema, each treated by thoracoplasty. The first was a man, thirty one years of age, who developed an abscess of the lower lobe of the right lung following the development of osteomyelitis in a compound fracture of the mandible. Failing to get results from postural drainage and medical treatment, a preliminary operation was done at which time portions of the third, fourth and fifth right ribs were removed and gauze inserted to produce pleural adhesions. A week later, after a blood transfusion, the abscess cavity was explored, heavy suture material inserted into the mesial side of the roof of the cavity, and a portion of the roof cut away. The cavity was wiped with plain gauze and packed with weak iodoform gauze. The wound and fistula closed and three months later appeared to be well healed without residual infection. The second case was of a boy, fourteen years of age, who developed an empyema of the left pleural cavity following lobar pneumonia in the spring of 1933. Drainage proving unsuccessful, a two-stage thoracoplasty was done, with the removal of almost all of the upper ten left ribs. Following the second stage, the wound healed completely and the patient, with no apparent residual infection, was shown, five months after the wound closed.

Following Dr Adams' discussion, group demonstrations were conducted in different portions of the hospital. The Drinker Respirator was demonstrated by Dr E L Amidon.

'Determination of the Basal Metabolic Rate' was explained by Dr A G Mackay, who also demonstrated the metabolism machine.

Dr W R Doane demonstrated the electrocardiograph and methods of making electrocardiograms.

The afternoon session came to a close with the exhibition of several reels of motion pictures which showed the normal heart and its conduction pathways, with special reference to the production of the waves seen on the electrocardiogram, and the experimental production of the various arrhythmias in a dog's heart.

The Saturday morning session opened with a discussion of the Parkinsonian syndrome by Dr T J Allen, Assistant Professor of Neurology. This symptom group was described as characteristic of paralysis agitans and as a frequent sequela of encephalitis. The neuropathology was briefly considered,

and the various symptoms were described with reference to their characteristics. Two cases were presented, one a case of paralysis agitans in a patient showing the beneficial effect of tincture of stramonium, the other a case of a postencephalitic subject who also was being helped by stramonium. Dr Allen exhibited a number of photographs of children showing the postencephalitic variety and of adults showing the changes resulting from paralysis agitans. Particular emphasis was placed in the discussion on stramonium and scopolamine.

The Department of Medicine devoted the next hour and a quarter to the consideration of the rheumatic, syphilitic, arteriosclerotic and toxic heart conditions. Dr P K French, Associate Professor of Medicine, conducted the symposium and presented cases illustrative of the various conditions. X-ray films and electrocardiograms of each case were shown and explained and a general consideration of treatment followed. The use of digitalis, and mercurial diuretics was explained in detail as well as the general management of cardiac cases. Dr C A Rarey spoke briefly on anesthetic treatment, and Dr A B Soule, Jr, on the roentgenologic aspects of heart disease. Dr C H Beecher led the general discussion which followed. In closing, Dr French emphasized the fact that, while very little beyond supportive measures could be done for the advanced cardiac case, the patients with the early and milder lesions should be helped, and greater effort should be turned toward the case of this type of patient.

During the next hour, the Department of Surgery, under the direction of Dr Lyman Allen, Professor of Surgery, presented a group of unusual surgical cases, and Dr Allen spoke briefly on abdominal surgical emergencies. Dr Allen listed the commoner conditions which are ordinarily classed as abdominal emergencies and commented on some of the characteristic features of each. Among the things emphasized by Dr Allen were the following: Cathartics, especially castor oil are dangerous where appendicitis or obstruction is suspected; morphine, since it masks symptoms, should be given with caution if at all, the patient should be taken to the hospital as soon as possible as the mortality rises with every hour's delay; a carefully made though brief history of the attack should be made, noting the signs and symptoms in order of their occurrence, and this should be sent to the hospital with the patient, together with a history of previous abdominal symptoms known to the family physician.

Dr G M Sabin next presented three cases of fracture of the vertebral bodies, two with compression fractures of the lumbar vertebrae, and one with fracture of the twelfth dorsal vertebra and complete lateral dislocation all with complete recovery of sensation and motor control. X-ray films, lantern slides and the patients themselves were shown.

Dr W T Rees and Dr Lyman Allen then showed a man who had had a cholecystostomy in 1927, at which time the gall bladder walls were greatly

thickened and gangrenous and the gall bladder itself contained purulent fluid and thirty-one stones, in 1931, due to recurring jaundice, the gall bladder was again explored by Dr Rees, who found the cystic and hepatic ducts and remains of the gall bladder distended, being unable to reach the common duct on account of adhesions, a cholecystogastrostomy was done, followed by relief of jaundice. On February 8, 1933, on account of further recurrence of jaundice, a third operation had been done by Dr Allen who found that the stoma between the gall bladder and stomach had closed. A new and larger opening between the gall bladder and stomach was made, and the jaundice again disappeared.

Dr Rees then showed a woman who had received a lacerated and contused wound of the right arm from an automobile accident in 1932, with complete severance of the brachial artery, the median and ulnar nerves and biceps muscle. The operations for nerve suture and general repair were described and the patient demonstrated good return in function now eighteen months after the accident.

Dr Lyman Allen presented a case of a girl who had developed a gas bacillus infection following an appendectomy, and had been treated by serum therapy and wide incision. He also presented a case of extensive depressed fracture of the skull with hemiplegia, treated surgically, explaining the procedures followed. The hemiplegia had disappeared, but paralysis of the external rectus of the right eye persisted and was to be corrected by operation on the muscle.

Dr B. D. Adams next presented a case of fistula of the nose following basal cell cancer of a number of years duration which was repaired by use of a line-attached frontal flap by three stages. He also presented a case of plastic restoration of the lower lip following resection of an epithelioma of the lip. The operations done were briefly described.

The Obstetrics Department, as represented by Drs O. N. Eastman and H. A. Durfee demonstrated vaginal operative delivery technique using the anatomic manikin and an embalmed fetus. Podalic version by Potter's method and the Scanzoni operation were shown by Dr Eastman. Dr Durfee demonstrated simple low and mid forceps delivery and the use of the Piper forceps for the after-coming head. The relative merits of solid and fenestrated blades as well as the Klelland forceps were discussed and the advantages of true axis traction were

emphasized. A brief discussion of resuscitation methods followed, stress being laid on the use of the mucus aspirator and carbon dioxide-oxygen mixtures.

The meeting closed on Saturday, May 5, at 1 P. M.

VERMONT DEPARTMENT OF PUBLIC HEALTH

APRIL, 1934

The incidence of communicable disease for the month of April was as follows:

Chicken pox 153, diphtheria 1, measles 379, mumps 56, scarlet fever 37, typhoid fever 37, whooping cough 144 and tuberculosis 12.

During April, the Laboratory of Hygiene made a total of 1,542 examinations, classified in the following manner:

Examinations for diphtheria bacilli	86
" " Widal reaction of typhoid fever	33
" " undulant fever	26
" " gonococci in pus	95
" " tubercle bacilli	234
" " syphilis	472
" of water, chemical and bacteriological	71
" " water, bacteriological	199
" " milk, market	141
" " milk, submitted for chemical only	8
" " milk, submitted for microscopical only	102
" " foods	1
" " drugs	1
" for the courts, autopsies	1
" " the courts, miscellaneous	5
" of animal heads for evidence of rabies	1
" miscellaneous	63
Autopsies to complete death returns	1

The nurses in the Division of Poliomyelitis After-Care made fifty-six home visits. Two patients were admitted to the Audubon Hospital and one was discharged from this hospital. Two patients were admitted to the Children's Hospital. Eighteen new pieces of apparatus were fitted to patients and sixteen orthopedic corrections were made to shoes. The vocational worker of this division reports sales amounting to \$87.69 for the month.

NEW HAMPSHIRE MEDICAL SOCIETY

HOUSE OF DELEGATES

May 14, 15 and 16, 1934

THE House of Delegates convened at the Hotel Carpenter at Manchester, New Hampshire, on Monday evening, May 14, 1934, at seven-thirty o'clock in the evening

The meeting was called to order by Henry C Sanders, Jr., Vice-Speaker

Dr Sanders then called the roll, the following members being present

Robert J Graves, President
 Frederic P Lord, Vice-President
 Carleton R Metcalf, Secretary Treasurer
 Arthur M Fernald of Hampton
 Cleon W Colby of Exeter
 Charles H Parsons of Concord
 Clarence E Butterfield of Concord
 James B Woodman of Franklin
 Osmon H Hubbard of Keene
 Arthur W Hopkins of West Swanzey
 Kenneth Churchill of Lebanon
 Leslie Sycamore of Hanover
 Charles F Keeley of Claremont
 Henry C Sanders, Jr of Claremont.
 Roland J Joyce of Nashua
 Byron D Pease of Greenville
 Deering G Smith of Nashua
 George C Wilkins of Manchester
 Richard W Robinson of Laconia
 John R Perley of Laconia
 William J P Dye of Wolfeboro
 Francis J C Dube of Ossipee
 George C Rublee of Rochester
 Harry O Chesley of Dover

SPEAKER SANDERS The next business is the appointment of Committees I will appoint as the Committee on Credentials Dr James B Woodman of Franklin, Dr Kenneth Churchill of Lebanon and Dr John R Perley of Laconia, as the Committee on Officers' Reports Dr Deering G Smith, Dr Arthur W Hopkins and Dr John R Perley, as the Committee on Communications and Memorials Dr C H Parsons, Dr Kenneth Churchill and Dr George Rublee

Is the Committee on Credentials ready to report?

DR WOODMAN The credentials are in due form and the members are present

SPEAKER SANDERS The next order of business is the President's report

DR ROBERT J GRAVES I suppose every man who has been honored by election to the presidency of this ancient and honorable society has assumed office with the belief that there were many things which he could accomplish during his term for the good of the organization and of the public I was no exception

However, the ideas which I had last May for straightening out certain professional tangles

in the State and for advancing the interests of this Society in general, miscarried at about the end of the first month, to be supplanted by the mole of legislative wisdom, House Bill 417

Practically all of us in this Society were neophytes in such matters, but all showed a commendable willingness to cooperate with the State Relief Administration We almost at once were ready to function, but they were not It was not until after the turn of the year that the machinery began to click with a reasonable degree of smoothness Since then the cases have been much better handled, and the chief difficulties have arisen through misconception on the part of a very few of our members of the modus operandi of relief problems Personally I do not know yet whether Bill 417 taken as a whole and administered in a strict interpretation of its phraseology is good or bad I am inclined to believe that it is neither, altogether Its fundamental concept is sound, but no bill so radically departing from former procedure can properly function or be adequately evaluated when the time for setting up the machinery of administration is so short

With the ever-widening range of social and economic invasions into what were formerly strictly medical domains, a closer knit organization is essential for the preservation of our medical existence Dr Chesley ably advocated this last year in his presidential address

Now the president is in office but one year, and unless he be exceptional or has come up through the ranks of long time service in the House of Delegates and has served on important committees and the like, his term is likely to be nearly over before he has done more than kindle a few feeble fires which are without real effect in warming up the Society as a whole to the vital aspects of this problem

Not so the Secretary He is the real, continuing, motivating influence for our salvation

Few of us realize the amount of devoted energy which Dennis E Sullivan gave to our Society This was his avocation, this practically his only thought outside of his personal practice, his family and his church The importance of choosing wisely in the selection of his successor can hardly be overemphasized.

The time is coming when we cannot afford not to have an adequately paid full-time secretary, who will be constantly on the job, a triad of executive ability, political leadership and molder of public opinion

The matter of free clinics must have our ear-

nest consideration. A recent compilation by State departments reveals that there are over 11,000 school children showing one or more corrective defects. These are all below high-school age, in families actually unable to provide proper medical care for their children, and for these some way must be found to put them in the best possible condition for making a living and doing their work in the world.

However, year after year since 1919, the already existing agencies have obtained an ever increasing number of corrections. Confirming our belief that there is no necessity for setting up new procedures for handling this situation I wish to quote from a letter written by an official of the State Board of Education:

"Since the beginning of the school health program in 1919 by the State Board of Education, the development of the work has gone steadily forward. The success of the program is in no small way due to the wholehearted cooperation and support of the medical and dental professions. In practically every school district of the State where school nurses are employed, there exist pleasant and friendly relationships. Through these relationships advice and care are made possible for many children. We would regret exceedingly to see a program which has been firmly established interrupted or retarded at this time. Individual physicians, including specialists in various lines, have contributed generously of their skill and service, frequently with little or no remuneration. We have appreciated, too, their confidence and interest.

At the present time there are employed in the State forty-one (41) full-time school nurses whose time is divided between one or more school districts. Six (6) of these nurses serve Manchester. A single nurse frequently serves from five to ten districts. There are thirty-five (35) public health nurses whose duties include school nursing, and there are fifteen (15) part time school nurses and about seventy (70) school physicians."

These are but a few of the problems which have come up this year. They grow more complex month by month.

Report of the Secretary-Treasurer

To the Members of the House of Delegates of the New Hampshire Medical Society. The following report for the year 1933 is respectfully submitted:

Total Membership December 31 1933

PAID MEMBERSHIP

Belknap County	29
Carroll County	11
Cheshire County	27

Dennis E Sullivan, for the past twenty-eight years Secretary of the New Hampshire Medical Society, died on January 19, 1934. His work in behalf of our Society throughout this long period was painstaking and intelligent, his duties so manifold that they demanded continuous and aggressive effort. This is a fact, gentlemen, not fancy, reality, not euphemism. Dr Sullivan delegated little, he was so constituted that he preferred to do things himself. Though few realize it, he was literally on the job day in and day out. Our Society is greatly indebted, then, to Dr Sullivan for this faithful, untiring service.

We should record, also, with sincere regret, the death of two other officers of this Society during the past year.

Eugene B Eastman, Portsmouth
William H Leith Lancaster

At this annual meeting we are adding two names to the rôle of those who have been members for a continuous period of fifty years.

Leonard Jarvis, Claremont
George E Leete, Concord

Each of these men will receive a gold medal, suitably engraved, at the general meeting on Tuesday afternoon.

At the same time, the following New Hampshire physicians who have completed fifty years in practice will receive a cordial greeting from the Society.

Walter R Sanders, Derry Village
Roscoe G Blanchard, Dover
Charles W Adams, Franklin
Frank A Smith, Lebanon
Frank S Lovering, Moultonboro
Ezra C Chase, Plymouth
George W Nutter, Salmon Falls

I have wondered if a gold medal is the most suitable gift for a half century member. Most medals repose in top bureau drawers. Would it be more appropriate to award a silver loving cup, suitably engraved, which could be displayed on the mantel piece?

Men who are eligible this year to become affiliate members are as follows:

Albert S Dolloff, New Hampton
Frederick L Hawkins, Meredith
Joseph J Cobb, Berlin
Edward E Twombly, Colebrook
Henry M Wiggin, Whitefield
N F Cheever, Greenfield
A W Petit, Manchester
B G Moran, Nashua

President Graves appointed James J Powers, Manchester Anniversary Chairman, and David W Parker a member of the New England Medical Council with term expiring in 1936.

The President also appointed Carleton R Metcalf, Concord, as Secretary-Treasurer pro tem to carry on the duties of the late Dr Sullivan until a Secretary-Treasurer is duly elected at this meeting.

The President invited the County Secretaries to Concord last Fall for the usual conference. Lunch was served at the Eagle Hotel and a lengthy discussion ensued in regard to the State Welfare work, particularly in its relations to the doctors of the State. Miss Patch, Supervisor of the Welfare work, was present.

In a communication from the State Librarian last year an offer was made to cooperate with us in reorganizing and rejuvenating the medical books in the State Library. Of recent years the collection has consisted largely of obsolete textbooks which are practically never read.

Charles H Parsons, Concord, was asked to decide, after conference with the State Librarian, what action had better be taken in this matter. Doctor Parsons is here to night and, when the Speaker so elects, will read you his report.

I have in my home in Concord the records and annual reports of the State Society dating back nearly one hundred years. The reports in particular, are of value. They repose for many years in Doctor Sullivan's office, but it seems to me that they might well be housed in the State Library or in the Library of the New Hampshire Historical Society, unless one or both of these organizations already have a complete file.

Robert O Blood, Concord, has also been invited to read a report to the House of Delegates. At the request of the New England Obstetrical and Gynecological Society, Doctor Blood has considered the formation of a Committee within our group, similar to the Committee on Cancer, to consider the improvement within the State of these two special lines of medicine. The New England Society feels that the several States will tend more and more to regulate and socialize the care of women and children unless the doctors bestir themselves.

In this connection, one thinks of crippled children. The State Board of Education, through its school nurses, is searching out these unfortunate waifs and making arrangements for their hospital care. Is the ground being thoroughly covered? Are there still in the State, bedridden children who, under proper treatment, could become ambulatory? Should our Society definitely cooperate in this work and if so, how?

I have been somewhat disturbed by the inactivity of some of the units of the Women's Auxiliary to the New Hampshire Medical Society. I believe that the Women's Auxiliary is a worthwhile organization, that it should be nourished and encouraged. I know of one County Society that is ready this year to contribute \$25.00 to our Benevolence Fund if we wish it. This same County Society is also planning to award a cash prize annually to the outstanding nurse in the graduating class of each of the hospitals in this particular county, but such enthusiasm is not universal.

If it is to thrive and prosper, the Auxiliary needs a definite job. Would it be well to ask the ladies to do something each year for the Benevolence Fund? Is this another chore to pass on to the long suffering county secretaries?

The Benevolence Fund has now reached the respectable sum of \$640.51. For the benefit of newer delegates, may I explain that fifty cents is reserved from the annual dues of each member to create this fund. The income of the fund at the discretion of the Trustees, the President and the Secretary-Treasurer, may be used to render pecuniary aid to needy members who are ill, disabled or aged, or to needy widows and children of deceased members.

A few of the County Societies seem to have difficulty in getting suitable speakers for their meetings. Would it be feasible to establish a lecture bureau to minimize this difficulty, with the lecturers chosen from our own members?

The State Legislature sits next year, and in the ordinary course of events, numerous bills of medical concern will be presented. There have been instances in the past where Dr Sullivan has been the only member of the New Hampshire Medical Society to appear and to speak at an important hearing. This is wrong. There should be a small group of our officers or of our wiser colleagues who would be ready to attend these hearings in case of need.

In May, 1933, the House of Delegates voted that the Standing Committee on Amendments to the

Constitution and By Laws be authorized to prepare a model Constitution and By Laws for County Societies"

This new Constitution and By Laws has already been placed in the hands of the Committee on Officers Reports of which Deering G Smith, Nashua is Chairman

A booklet containing the Constitution and By Laws of our State Society was last published in 1927 Since then various changes in the by-laws have been made and the interpretation of a few has been in question A suggestion has been made that a new edition of this booklet be published within the next year or two for distribution among the members of our Society

Since Doctor Sullivan's death the scientific program for this year has been in the hands of Richard W Robinson Laconia and Frederick P Scribner Manchester They have worked hard, conferred often, and are presenting to you tomorrow and Wednesday a group of speakers who will meet with your entire approval I am extending to them my heartfelt thanks for relieving me at this time of this particular detail which ordinarily falls largely on the shoulders of the Secretary

To the County Secretaries also and to many other members of the Society I am greatly indebted for the cordial and prompt cooperation that has been given me in undertaking a new, uncharted and intricate task.

CARLETON R. METCALF
Secretary Treasurer

Reports of Councilors

BELKNAP COUNTY

The Belknap County Medical Society held six meetings during the year November to April inclusive The average attendance was higher than usual The year was unusual from the fact that we were able to secure several papers from the members of the society The society lost one member by death Dr N W MacMurphy of Belmont and gained three new members Drs Stewart, LaFrance and Hill

C S ABBOTT
Councilor

CARROLL COUNTY

During the past year the Carroll County Medical Society has held three meetings at the Center Ossipee Inn.

We were pleased to have Dr Graves with us at our August meeting In December Dr Gordon Morrison of Boston gave an excellent paper on some common fractures

At our last meeting in April papers were given by our own members

CHARLES E SMITH
Councilor

CHESHIRE COUNTY

The Cheshire County Medical Society had a very quiet year in 1933 and there is practically nothing to report to the State Society

A. A. PRATTIE,
Councilor

COOS COUNTY

The Coos County Medical Society has held two meetings the past year as usual one in the Fall and one in the Spring These meetings have been well attended and helpful.

All the physicians of the county are enrolled in its membership but there are a few whom one never sees at a meeting This is unfortunate for the society but even more so for the absent members as

I believe there is much to be gained in these meetings for every practitioner

Our programs are made up mostly with the aid of outside speakers It is regrettable that our own men are so loath to write and read papers, notwithstanding the fact that there are no abler men in the profession than those found here in our northernmost county

RICHARD E. WILDER
Councilor

GRAFTON COUNTY

The Spring meeting was held at the Littleton Hospital and the members were guests of the Hospital Trustees at luncheon, following the meeting An inspection of the rebuilt hospital was made at this time

The program was furnished by the Littleton members There was a good attendance

The annual meeting was held in Hanover at the Marv Hitchcock Hospital The usual business was disposed of and the members were luncheon guests of the Hospital and Trustees The meeting was held in the assembly room of the Dick Hall House where the society was given a most instructive talk on Endocrinology, by Doctor Reginald Fitz of the Harvard Medical School

A. T. DOWNING,
Councilor

HILLSBOROUGH COUNTY

The Hillsborough County Medical Society during the last year had the largest membership it has had in many years We have lost three members by death during this time

The fall meeting was held at the Hillsborough County Hospital Clinics were held and cases demonstrated after which by the courtesy of the County Commissioners we were served a very fine dinner

In the afternoon Mr E H Hunter of Hanover outlined the present welfare situation that is being carried out in this state There was great interest and much discussion over this topic

There were also papers by Dr G C Wilkins of Manchester and Dr R H Southwick of Boston

The spring meeting was held at Wilton N H and after business was transacted Dr Norman W Crisp of Nashua gave a paper on Surgical Lesions of the Stomach and Duodenum and Dr James P O'Hare of Boston gave a talk on Uremia and Hypertensive Encephalopathy

Luncheon was served with the compliments of David Whiting & Sons Inc. and the entire meeting including the Women's Auxiliary was given a trip through the Hampshire Hills Dairy, where the production of certified milk was shown in the ultra-modern milking parlor Dr Richard S Eustis of Boston gave a talk on Vitamin Milks and the different methods of production

This year the County has had a relations committee to act as an intermediary between the welfare activities and the physician. There have been many controversies and problems brought to its attention which were satisfactorily handled through this committee

CLARENCE O. COBURN
Councilor

MERRIMACK COUNTY

The Center District & Merrimack County Medical Society has held four meetings during the past year, all at the Eagle Hotel Concord N H

July 19 1933 The general subject of Medical Care of the County Poor was discussed by Dr R J Graves President of the New Hampshire Medical Society and by Dr D E Sullivan

October 5, 1933, at an open meeting the subject of medical relief was discussed. Dr Graves presented the subject of thyroidectomy for relief of angina.

At the annual meeting January 5, 1934, Dr T P Burroughs, City Health Officer, read an interesting paper on the general subject of public health.

Officers elected

President, Dr W. C. Rowe, Concord.

Vice President, Dr J B Woodman, Franklin.

Secretary Treasurer, Dr C H Parsons, Concord

On April 4, 1934 Dr R E Miller of Hanover gave an address on Cancer

The Society has admitted to membership during the year, Dr Norris of New London, Dr McCarthy of Concord, and Dr LeBlanc of Suncook

We note with special regret the death of Dr D E Sullivan

H. H. AMSDEN,
Councilor

ROCKINGHAM COUNTY

During the past year two meetings were held. The annual meeting was in October at the County Building, Exeter. Exceptionally valuable and interesting papers were presented by Doctors Herbert L. Taylor, L R Hazzard, and E A Vickery all of Portsmouth and Dr D E Higgins of Epping.

Our late and lamented Secretary, Dr D E Sullivan, was present and shared in the discussion of the papers. Possibly he flattered us a bit when he said that it was one of the best County meetings he ever attended that all the papers were by local members and all worthy of appearance in the state program.

The Spring meeting was held at the Portsmouth Hospital in April. After some business and presentation of dry clinic cases by members, Dr Chester F McGill demonstrated in rabbits the Aschheim Zondek Reaction. It was interesting, convincing and novel to most of us.

At 11 00 A M Dr Edward DeLos Churchill of the Massachusetts General Hospital read a wonderful paper on Thoracic Surgery and kindly answered many questions relating to modern methods. A generous luncheon was served at the hospital.

In the afternoon Dr Robert L DeNormandie delivered an address "Obstetrics in Retrospect." To us older members it was like reviewing the scenes and experiences of childhood. To the younger probably much seemed strange if not improbable. Yet in that period most patients, both mother and baby, survived.

Since our last report death has claimed two active, strong members our President Dr Eugene B Eastman, Portsmouth and Dr Joseph C Tappan, Derry.

The addition of one new member makes our net loss one.

ABRAHAM W MITCHELL,
Councilor

STRAFFORD COUNTY

Three meetings of the Strafford County Medical Society were held during the year 1933. The first meeting was on July 25 at the American House, Dover N H., at which time there was a very active general discussion relative to the attitude of the members of this society toward the welfare work and it was decided to lay the matter on the table for the present.

On August 4 the above meeting was continued with Dr Robert Graves state president, as well as the late Dr Sullivan secretary. Once again this matter of the fees and cooperation with the state relative to the poor, etc., was carefully gone into and it

was finally voted after a lengthy discussion to accept the scale of fees other societies had taken.

On November 9 the annual meeting was held at the Gray Tower Motor Inn at Rochester, N H. Following the election of officers, Dr Lewis M Hursthal (Boston) gave a very interesting paper on the "Mechanism of the Heart Beat."

This was followed by a general discussion. Three new members were voted into the Strafford County Medical Society, Dr W E Precourt, Somersworth, Dr Prince, Durham and Dr W B Rahmanop, Dover.

We are sorry to report the death of Dr A E Grant of Durham on December 8 from mesenteric thrombosis.

J A. HUNTER,
Councilor

SULLIVAN COUNTY

The Sullivan County Medical Society has enjoyed its usual amount of activity during the past year. At a meeting in the summer, held in Claremont, Dr Graves, President of the State Society, and Dr Sullivan, Secretary, were present and outlined the work to be undertaken by the state welfare. The question of a fee table for the welfare cases was discussed and it was voted to accept the table adopted by the State Society.

The annual meeting was held in Claremont in December, at which time a paper was read by Dr Hau brich of Claremont and discussed by various members of the society. The meetings were well attended and much interest was shown in the general proceedings.

EMERY M. FITCH,
Councilor

SPEAKER SANDERS Dr Syvertsen has a report which he would like to make.

DR. SYVERTSEN During one of the meetings of the Welfare Council held at Concord, it was announced that a fund of \$40,000 had been obtained from the Federal Government to serve as a work relief project to employ forty nurses for a year, or the larger part of a year. This fund, and this personnel of nurses, were to be used in making a state-wide survey of remediable physical defects among the children in the State, under high-school age. I was asked to serve on the Committee to supervise the work of this group. Mr Pringle of the State Board of Education, Dr Kerr and Mrs Abbie L Wilder, the Federal Employment Director, were also members of this Committee. After the appointment of this Committee, and in fact on that very day, we had a meeting and decided that it would be regrettable if a large new agency were set up in the State to spend this \$40,000 entirely in the work of making a survey, when, in all probability, all data were available in the records of either the State Board of Health or the State Board of Education.

So, we proceeded, with the assumption that if the data from such a survey could be presented to the authorities in Washington, it might be possible to salvage this fund, for use in actual work.

In proceeding with this assumption, Dr Dun-

can's office and Mr Pringle's office were asked to canvass their workers throughout the State and to assemble at Concord the necessary information. This survey was partly completed, when Dr Ellhott, from the Children's Bureau in Washington came to Concord to confer with us, and we were able to convince her, at least temporarily, that the survey was proceeding with sufficient success to assume the possibility that it would not be necessary to spend any of this money in acquiring data.

When the survey was finally completed a member of the Committee took it to Washington and secured the promise that we might use the \$40,000 in corrective work.

It was felt by the Committee that it would be extremely undesirable in view of the already existing agencies to establish any new group for the purpose of doing something which could be possibly done by organizations in existence. With that idea in mind we decided to analyze our data. We found that in the State there were some 11,813 children reported as afflicted with remediable defects that might be corrected.

It has been the feeling of the Committee that there are, in the state, agencies which could take care of these defects with the funds which have been available in the past and are still available, and if it is actually merely a matter of funds it is possible that by subsidy, or by subsidizing these agencies with this money, the program can be continued to a satisfactory conclusion.

We expect that if we can have the whole-hearted cooperation and encouragement of the State Medical and Dental Societies, with this money a large forward step can be made toward correcting this problem.

As Chairman of this Committee, I would like to ask the New Hampshire Medical Society to give us this whole-hearted cooperation and encouragement, because all of this work should spring from and be initiated in the State Society, and, if we are to obviate the entrance into the field of large lay groups that are equally concerned with this matter we must make some sort of a movement in the right direction.

I would like to ask some one if he will make a motion, that a Committee of three be appointed by the President, to be known as the Child Health Committee of the New Hampshire Medical Society and further that a similar committee be established in each county to function in a respective manner for the county.

DR. ROBERT J. GRAVES. I would like to make the motion which Dr Svendsen has suggested.

DR. FREDERIC P. LORD. I would like to second the motion, and to express my own feeling that it should be a separate committee of three

SPEAKER SANDERS. It has been moved and seconded that a Committee of three be appointed by the President, to be known as the Child Health Committee of the New Hampshire Medical Society, which shall act for the society in the emergency matters concerning child health, and which shall serve as the beginning toward cooperation with and coordination of all agencies within and without the State, which are concerned with Child Health, and, further, that a similar committee be established in each county to function in a respective manner for the counties. This committee shall serve for one year. The motion was carried.

Report on State Library

DR. C. H. PARSONS. The books and periodicals in the New Hampshire State Library were carefully checked over, with the cooperation of Miss Thelma Brackett, the State Librarian. The books were found to consist of two groups, those of some slight historical interest, and those which were entirely worthless for any purpose, the latter being in the majority. It was found that the books had been borrowed very infrequently, that they had been consulted in the Library very infrequently. The periodicals were not of a great deal of practical value.

With the cooperation of Miss Brackett, many of the textbooks were discarded. The majority of the periodicals in the files were discarded. The following journals were subscribed to:

American Journal of Diseases of Children
American Journal of Psychiatry
American Journal of Medical Sciences
Archives of Internal Medicine
New England Journal of Medicine

These were subscribed to because they were the journals that were most frequently requested by the very few physicians who came into the Library.

It was decided that it was inadvisable to purchase any medical textbooks.

SPEAKER SANDERS. I will now call for the various reports. I believe that Dr Metcalf has two reports to give us.

Report of the Committee on Scientific Work

Your Committee met several times to arrange the program for the annual meeting, the earlier meetings being held before Dr Sullivan's death. The Committee has conferred also with the President of the Society with County Secretaries and with individual members.

The Committee would like to learn of suitable original papers which are read at meetings of the County Societies. Many of them could be re-read with profit at the annual meeting of the State Society. In an effort to unearth new material a postal card was recently sent to each member of the Society suggesting that he or she prepare a paper for 1935 or 1936.

The program for this year's annual meeting has been printed and distributed to the entire membership as usual

RICHARD W. ROBINSON,
FREDERICK P. SCRIBNER,
CARLETON R. METCALF

Report of the Committee on Publications

The contract with the *New England Journal of Medicine* has been continued during the past year. The *Journal* gives our Society a definite number of pages in its first edition each month, and prints our Annual Transactions. Each paid up member of our Society receives one copy of the *Journal* a month.

We are anxious to have the county societies send, for publication in the *Journal*, papers read at their meetings, news items, case reports and similar material.

Secretaries of the several County Societies are urged to cooperate in this matter.

BENJAMIN P. BURPEE,
LAWRENCE R. HAZZARD,
CARLETON R. METCALF

Report of the Committee on Constitution and By-Laws

In May, 1933, the House of Delegates voted that "The Standing Committee on Amendments to the Constitution and By-Laws be authorized to prepare a model Constitution and By-Laws for County Societies."

In accordance with this vote, the Committee has prepared a Constitution and By-Laws (herewith submitted) based on the model prepared by the Committee of the American Medical Association, but with several important modifications. It is nearly identical with the present Constitution and By-Laws of the Hillsborough County Medical Society, which were adopted in 1929.

HENRY O. SMITH,
THOMAS W. LUCE,
FRED E. CLOW

SPEAKER SANDERS Will Dr Henry O Smith please be kind enough to summarize the report

DR. HENRY O. SMITH The model Constitution, adopted by the American Medical Association, formed the basis of the Constitution and By-Laws adopted, but with quite a few modifications. With reference to business matters, there were several changes looking to a more simple method of doing business. For instance, in the model constitution, as recommended by the American Medical Association, the Treasurer was allowed to pay bills, only on the order of the President, countersigned by the Secretary, and on various other matters, it seemed to us that unnecessary verbiage and unnecessary work were entailed.

The chief addition that your Committee embodied was this, that the delegates to this House should be elected for a two-year term. I would like to say that this was the one change that Dr Sullivan was very anxious to see incorporated in our by-laws, because that would seem to insure the presence, in our House, of at least fifty per cent of the members with experience.

SPEAKER SANDERS This report is auto-

matically referred to the Committee on Officers' Reports.

Dr Parker now has a report to make.

DR. DAVID W. PARKER It has always been my judgment that the New England Medical Council has been, and is, of definite value to the New Hampshire Medical Society, and to the medical societies of the several States of New England, because this organization furnishes the opportunity for the representatives of these several societies to discuss and act upon problems which are of equal interest to the medical profession of all the States. Not infrequently, these problems are of paramount importance, and can be successfully solved only by concerted action of the representatives of these several State societies. It is my feeling that the Council has justified its existence by its action on the prevention of malpractice suits, and its clarification of the problem of reciprocity between States.

There has been a feeling on the part of several of the State delegations that the assessments for expenses should be based on the membership of the several State societies. The organization of this body is analogous to that of the Senate—that is, equal representation from each State, regardless of the membership of the State society. On that basis it has seemed to me fair and equitable that the expense of the organization should be borne equally by the several States, especially as these expenses are not heavy.

It would seem to me that the continuance of this organization might be of distinct future value to our Society.

DR. FREDERIC P. LORD Mr Speaker, I would like to ask Dr Parker if the New England Medical Council is defunct and will not meet unless something is done?

DR. PARKER From this letter of Dr Bowers, I assume that is a fact, unless the State Societies do express a desire to have it continued. My reaction was that if we passed favorably on that, and forwarded our decision to Dr Bowers, it might be brought up before the other State Societies and they might take action on it, that is, to perpetuate it, on this plan.

DR. LORD What is the extent of the contribution?

DR. PARKER Each society appropriates one hundred dollars, but I can't tell you what the actual expense is.

SPEAKER SANDERS This report will be automatically referred to the Committee on Reports. I will now call upon Dr Smith for further reports at this time.

DR DEERING G. SMITH The special committee on Medical Liability Insurance has had the subject under consideration for two years. We have sought advice from representatives of insurance companies, in conference and by mail, with officers and members of your society, as well as from a similar committee in Vermont. Our report falls into two sections.

I Advisory Committee on Medical Jurisprudence

Your committee is of the opinion that the name and definition of the duties of the Committee on Medical Jurisprudence could, with advantage to us all be changed. The scope of activity of the committee should be broadened to include friendly arbitration between physician and physician as well as between patient and physician. It should include arbitration between patient and physician before the stage of legal action begins. The name should be changed so that it will indicate these improvements.

Your committee believes that procedures within the committee and the conduct of hearings could be modified with the result that any accused man would be inclined more than at present, to bring his troubles promptly and candidly to a group who will listen sympathetically without outside aid or influence. The latter suggestion can be adopted by the group without legislation. The committee on jurisprudence should give aid and assistance to men insured in any company or association or who are not insured at all. The benefits of the committee should be available to our members without exception.

II The Insurance Group

The group of men insured in the company recommended by the society varies in size but has a tendency to grow smaller. Many factors enter into the cause of this situation: prohibitive expense of any insurance in these days of depleted incomes, the particular company with which we have done business, the attitude of the local agent, past experience and a number of other reasons prevent the growth we had hoped. Nothing can be done as missionary work save in the smaller groups of men meeting in the county society to overcome these objections. Many of the men who have left the group attend no society meetings.

Your committee studied the Vermont Plan where each member of the State society is automatically protected in suits with insurance purchased by him self to cover judgments and settlements. It is evidently impossible to establish this plan in our State. Vermont has a homogeneous and coherent membership. Every man is doing his part to lessen the incidence of suits and threatened suits. The plan has been operating for years and a comfortable surplus has been accumulated. Your committee can but express its regret that New Hampshire has not a similar plan. The more closely men are allied in an enterprise of this sort, the keener the individual vigilance upon which all success must be founded.

Recommendations 1 We recommend that the name and definition of the Advisory Committee on Medical Jurisprudence be changed after study by the Committee and the Committee on Constitution and By Laws.

2 We recommend that since some expense has been incurred but no bills have been rendered the appropriation of last year (one hundred dollars) be voted again for the purposes of this Committee.

3 We recommend that the Committee be continued for one year.

FEED E. CLOW
DEERING G. SMITH
RICHARD ROBINSON

SPEAKER SANDERS I will now call for further reports of various committees, the first being the Committee on Tuberculosis.

Report of the Committee on Tuberculosis

It is in many ways a remarkable fact that after four years of serious economic depression, the tuberculosis death rate should continue its declining trend for much historical and present-day discussion has stressed the close relation between the tuberculosis death rate and economic and social conditions.

For the year 1920 the tuberculosis death rate was 97 per 100,000 in the State of New Hampshire. In the year 1925 the rate had declined to 66. In 1930 to 53.1 and in 1932 to 44.9—the lowest in the New England States and one of the lowest in all the States of the Union. The figures for 1933 are not as yet available but there is reasonable expectation that the phenomenal reductions will be maintained and added to in 1933.

During the years of normal economic conditions and in periods of economic prosperity the reductions in the tuberculosis death rate have been ascribed in a greater or lesser degree to the improvement in standards of living for the masses of the people, particularly among the workers in industry. If the all important factor is improved living conditions then the past four years of distress should be witnessing increasing morbidity and mortality from tuberculosis. Yet there is no definite evidence to indicate such a tendency. On the other hand we know that the 'development of tuberculosis' is not an overnight matter; that the manifesting of active tuberculosis disease occurs in the great majority of cases only after a long period of combat between the tuberculosis germs and the tissues of the human beings in whom they have become established. How long this period of attrition may be is hard to estimate, but in many cases a matter of months and years. It is easily conceivable that the physical and mental distress suffered by the people in these past four difficult years may yet manifest itself in the years ahead in increased prevalence of and deaths from tuberculosis.

However we have every reason to feel that the forces for the control of tuberculosis among the people of New Hampshire have been so well organized and coordinated as to take care, not only of the usual tuberculosis load but also of any accretions resulting from the economic depression. The effect of the work of the last twenty or twenty-five years has been cumulative in character. The people of New Hampshire, through the legislative bodies, have been alert to the necessity for caring for the tuberculous. Philanthropic and public spirited citizens have given of their means to finance the tuberculosis campaign in the field through the work of the tuberculosis clinics and nurses. Public health agencies of New Hampshire have been active participants in the tuberculosis campaign. The medical profession of the State has been increasingly active and is becoming more and more skilled in the diagnosis and treatment of the disease. Our sanatoria are expanding their facilities and their service in arresting tuberculosis and in restoring patients to working capacity on a large scale. Their annual contribution to the saving of lives is a large one and very tangible. Of recent years pneumothorax, phrenicotomy and thoracoplasty are being used as valuable adjuncts to sanatorium treatment in certain types of cases.

Our own sanatorium at Glenciff has employed these additional methods of treatment with promising results.

There is a waiting list for admission to both sanatoria at Glenciff and Pembroke but the interval between application and admission is not a lengthy

one In our neighboring State of Massachusetts the waiting period is about four months behind the application for admission in many of the county sanatoria

The large reduction in tuberculosis deaths during the past fifteen years in the State means that there are fewer advanced cases capable of producing new infections and victims in the community. Fewer infections means fewer active cases in later years. There is thus set up a beneficent circle which serves to protect the community.

It is apparent, however, that any breakdown in the intensive program of tuberculosis control through out the State would be a tragic circumstance at this time. It is a cause for considerable gratification that the intensive program is to be continued and that the service has the active participation of the physicians of the State.

Respectfully submitted,

R. B. KERR, Manchester,
R. M. DEMING, Glencliff
A. L. WALLACE, Nashua

Report of the Committee on Mental and Social Hygiene

The last decade has witnessed a definite change in the attitude of the profession toward psychiatry. Before then psychiatric problems were considered by the average medical man to be of an occult nature smacking of mysticism and metaphysics with little of scientific background to make them attractive and the psychiatrist was rated more as a custodian of demented and defective than as a practitioner of medicine. To-day psychiatry not only ranks as one of the important specialties of medicine but it is so definitely interwoven with the etiology and treatment of all other forms of disease as to suggest that no all-round medical man can afford to

ignore altogether the psychiatric point of view. The personality make-up of a patient suffering from hyperthyroidism, hypertension, angina pectoris or gastrointestinal disturbances is often of the greatest importance in the etiology. Every urologist now knows that impotence is frequently not of organic origin and that the pediatrician certainly needs some help or understanding in dealing with the behavior problems of his children. For these reasons, medical schools are devoting a great deal more time to neuropsychiatry and many are requiring first hand acquaintance with a certain number of such cases before graduation.

The general practitioner, however, as a rule, has taken little advantage of the recent advances in psychiatric research and treatment, and to him the state hospital oftentimes still remains just an insane asylum.

The clinical facilities of the New Hampshire State Hospital are open to the medical profession of our state and the general practitioner is invited to visit the hospital and make the rounds with the members of the hospital staff. Such visits would act as a stimulating influence on the hospital staff, and at the same time would serve to acquaint the visitor with modern methods of treatment and care in mental hospitals.

In the past five years the daily average of our State Hospital has increased 235. This is largely due to the fact that many patients with only slight mental damage are now being sent to the hospital. Whether the burden of caring for many of this type belongs upon the hospital is open to question. During the past year twenty eight patients were considered to have no psychosis.

In several instances, committing physicians have failed to carry out the commitment procedure required by law. In a few cases the patient at the time of commitment was not seen at all by one of the physicians, and in two instances during the past year, lawsuits have been instituted on the grounds of illegal commitment.

Every case that now leaves the hospital is discharged on probation, and is returnable at any time within six months without a new commitment. The law should be changed, lengthening the parole period to one year.

In order to treat successfully mental disorders, early diagnosis is important, and to prevent mental disease, the correction of faulty mental trends must be recognized in the child or adolescent.

Mental hygiene clinics for the prevention and treatment of incipient cases are now being established at strategic points of the state but these cannot be established and maintained without sufficient funds being appropriated to support them.

The establishment of a children's ward at the State Hospital, devoted primarily to the study of neuropsychiatric conditions in children is an outstanding need in the mental hygiene program of the state. In order that such a ward may function successfully, the cooperation of the medical profession is required. Sterilizations are still being done at the State Hospital and State School as a contribution to the prevention program.

CHARLES H. DOLLOFF
For the Committee

SPEAKER SANDERS Is there any new business to come before the meeting?

Report of the Committee on Public Relations, Public Policy and Legislation

The Committee on Public Relations, Public Policy and Legislation of the New Hampshire Medical Society has held no meetings for we felt that for

any activities before the General Court at its next meeting a concerted program and definite action should be taken with the elected members of the General Court, so that when these different projects will be brought to their attention, we would have friends to deal with rather than coming into General Court as strangers

SAMUEL T. LADD
Chairman of the Committee

SPEAKER SANDERS At this time, I will call upon Dr. George C. Wilkins to give the report of the Committee on Control of Cancer

Report of the Committee on Control of Cancer

During the past year your committee has distributed less literature to the medical profession and nurses because of the withdrawal of free distribution by the American Society for the Control of Cancer. This Society will continue to furnish pamphlets at the request of the committee or at the request of any physician but owing to the necessity for retrenchment it has been obliged to apply what amounts to a cost charge when pamphlets are furnished. Your committee has limited its distribution to two letter sheets containing short but pointed observations on cancer diagnosis and care. We feel that distribution to the medical profession of pertinent information in a short, easily read form is an admirable way to disseminate cancer information. Whether this gratuitous information is appreciated or even wanted by the physicians of the State, we have no way of knowing. Only one comment has been received during the past year by any member of the committee from any member of the medical society.

Your committee was twice invited by Governor Winant to conferences with the State Cancer Commission and was able to offer helpful suggestions in the formation of the various cancer clinics which have been sponsored by the commission through the State Board of Health. We believe that these ten clinics in the State will become the nucleus of a group of men who are honestly interested in early cancer diagnosis and early treatment. We believe these groups consisting of members of our society will have an important part in educating both the laity and the physicians in developing a proper attitude toward early and correct diagnosis. It should be borne in mind by every member of the Medical Society that these clinics offer assistance to any doctor in the State in helping him to make a diagnosis in suspected cancer. They are equipped to make biopsies, laboratory examinations and x-ray diagnoses.

A year ago your committee recommended that every county society be requested to devote one meeting of the year to a symposium on cancer with special reference to diagnosis and selective methods of treatment. Your committee has no information at hand as to whether this suggestion was accepted by the county societies but this year we reiterate the importance of such a program and hope the county societies will carry out this recommendation during the ensuing year.

Your committee has not expended the seventy-five dollars (\$75.00) appropriated last year as there was an unexpended balance from the previous year which has been available and which is now exhausted. The committee requests an appropriation of fifty dollars (\$50.00) for the following year:

GEORGE C. WILKINS
GEORGE F. DWYELL,
HOWARD N. KINGFORD

SPEAKER SANDERS Is there any new business to come before the meeting?

DR. D. G. SMITH Due to the fact that no provision has been made for remitting the dues of the members of our societies who are totally disabled before they reach the age of sixty-five (65), the Hillsborough County Medical Society on April 10, 1934 voted

1 That our delegates to the New Hampshire Medical Society be instructed to propose the following amendment to Chapter 1, Section 5 of the By-Laws: insert "and" in place of the comma after "years", insert "either" after the first "is" in line two, insert "or totally disabled" after "age", strike out "or who is an honorary member of his component society in an equivalent manner whereby he is relieved from the payment of dues," so that this section will read "Any physician who has been a member of this society for a continuous term of fifteen years, and who is either not less than sixty-five years of age or totally disabled, on the request of his county society may be made an affiliate member by a majority vote of the House of Delegates. Affiliate members shall be privileged to participate in the meetings of this Society but shall not be required to pay dues."

2 That a similar amendment to our by-laws be proposed

Accordingly, Mr. Speaker, I propose this amendment to the State Constitution and By-Laws

SPEAKER SANDERS This will be referred to the Committee on Constitution and By-Laws

Is there any further new business to come before the House of Delegates?

DR. GRAVES The complexity of the problems which have arisen makes me believe that the House of Delegates should authorize the appointment of a committee to have a certain amount of authority in dealing with the State Welfare Administrative Board Officials

DR. LORD In pursuance of Dr. Graves' idea, I would like to make this motion, that the Speaker of the House appoint three members of this Society to serve for one year as a Committee on State Medical Relief, whose function shall be to act with power for the New Hampshire Medical Society on matters concerning State Medical Relief

This motion was seconded by Dr. Wilkins. Upon vote, Dr. Lord's motion was unanimously passed.

DR. DEERING G. SMITH Mr. Speaker, because of the conflict in the By-Laws of the State Society where, in Section 5, it says, "The Trustees shall be the custodians of all funds belong-

ing to the society," and where, in Section 1, Chapter II of the By-Laws, it says that the "control, investing power (and so on) of the funds of the Benevolent Fund shall be in the hands of the Trustees, the President and Secretary-Treasurer", I propose the following amendment to Section 1, Chapter XI of the By-Laws, that the words "control, investing power, and" be stricken out of the second sentence, so that it will read, "The distribution of the income shall be vested in a Committee whose members shall consist of the Trustees of the Society, the President and the Secretary-Treasurer" Now, all that means is that the Benevolent Fund shall be under the control of the Trustees, as are all other funds of the Society

SPEAKER SANDERS This will be referred to the Committee on Constitution and By-Laws

DR SMITH I wish to give a partial report of the Committee on Officers' Reports

On the Report of the Secretary Treasurer, we wish to commend Dr Metcalf for the able manner in which he has carried on the work of Secretary Treasurer since the regrettable death of Dr Sullivan. We recommend the acceptance of this report and its incorporation into the Transactions of this Society.

We desire to call particular attention to the reference made to Dr Sullivan.

We recommend that the old records and annual reports of the society be housed in either the State Library or in the Library of the New Hampshire Historical Society, the choice to be made by the President and Secretary.

We do not believe it to be feasible at this time to establish a lecture bureau.

We recommend that the Constitution and By-Laws of this Society be published in booklet form, as soon as possible.

On the Report of the Committee on Amendments to the Constitution and By-Laws, we recommend the acceptance of this report and its incorporation into the Transactions of this Society.

We believe that each county society should adopt the model constitution and bylaws recommended by this Committee. We urge that each county society elect its delegates for a two-year term, and that at least one delegate be elected each year. We recommend that the State Secretary send a copy of the above model Constitution to each county secretary.

On the Report of the Committee on Mental and Social Hygiene, we recommend the acceptance of this report and its incorporation into the Transactions of this Society.

We recommend that the suggestions relating to the length of the parole of mental patients, clinics and children's ward be referred to the Committee on Public Relations, Public Policy and Legislation.

On the Report of the Committee on Scientific Work, we recommend the acceptance of this report and its incorporation into the Transactions of this Society.

We recommend that commendation be given to the members of this committee for the excellent program that they have prepared, and, for the efforts that they are making to have original papers presented by members of our Society.

On the following reports, Report of the Committee

on Publications, Report of the Necrologist, Report of Dr Parsons, relative to the State Library, Report of the Committee on Tuberculosis, Report of the Committee on Public Relations, Public Policy and Legislation, and Report of the Committee on Medical Liability Insurance, we recommend the acceptance of the reports and the incorporation into the Transactions of this Society.

We further recommend that the name of the Advisory Committee on Jurisprudence be changed to the Committee on Conciliation, and that the Chapter IX of the By-Laws be rewritten to conform with the ideas embodied in Section I of this report.

On the Report of the Committee on the Control of Cancer, we recommend the acceptance of this report and its incorporation into the Transactions of this Society.

We also recommend the continuance of this work and the appropriation of Fifty Dollars (\$50.00) asked for by the Committee.

On the Report of the New England Medical Council, we recommend the acceptance of this report and its incorporation into the Transactions of this Society.

Action on this matter has already been taken by the House of Delegates.

On the President's Report, we recommend the acceptance of this report and its incorporation into the Transactions of this Society.

We wish to thank Dr Graves for the tremendous amount of energy and time that he has spent in representing us in our relations with the Relief Administration.

We commend to the earnest consideration of the members of the Society the various subjects so ably discussed by the doctor in his report.

SPEAKER SANDERS You have heard a partial report of the Committee on Officers' Reports. Is there any motion regarding this partial report?

DR. WILKINS Mr Speaker, it appears that in that report there are no controversial subjects, and, in view of that fact, it seems to me unnecessary to vote on each recommendation separately.

I, therefore, move you, Mr Speaker, that all of the recommendations be accepted and adopted.

This motion was seconded and was carried.

SPEAKER SANDERS Has anybody anything to say about the New England Medical Council?

DR WILKINS I don't want to take up all the time, but I really feel that the New England Medical Council is an important institution, and we perhaps, as New Hampshire members of the profession, have a peculiar interest in it, because we were the ones who suggested this change and this contact with the other medical societies of the six New England states. I have sat in at a good many of the meetings, and I honestly believe that the Council accomplished something for the good of the medical profession of New Hampshire, perhaps not so much as we would hope, but I do believe that we ought not to allow it to die unless it dies with the

active coöperation of all the societies, too I would move you that this House of Delegates should indicate how they feel about it, and then the committee can act accordingly. I think it is sufficiently important for the members of the House of Delegates to act upon

SPEAKER SANDERS Dr Parker's recommendation is as follows "I would, therefore recommend that the New Hampshire Medical Society go on record as favoring the continuance of the New England Medical Council, under its present organization, and that meetings be held at no regular stated intervals, but at the call of the President and the Executive Committee when any problem or problems may arise which in their judgment, justify the expense of such a meeting, and that the expenses of such meetings be borne equally by the several states "

This motion was seconded and was carried

DR ROBINSON I move you, Mr Speaker, that we adjourn

This motion was seconded and was carried

SPEAKER SANDERS We will now adjourn until to-morrow morning at eight-thirty o'clock in this room

Adjourned, at nine-fifty-five o'clock in the evening

TUESDAY, MAY 15

The House of Delegates convened for its second meeting at the Hotel Carpenter, Manchester, New Hampshire, on Tuesday morning, May 15, 1934, at eight-thirty o'clock

The meeting was called to order by Dr Henry C Sanders, Jr, Vice Speaker

SPEAKER SANDERS There are twenty members present, which number constitutes a quorum

The next business is the reading of the minutes of the last meeting

DR WILKINS I move that the reading of the minutes of the last meeting be omitted

This motion was seconded and was carried

SPEAKER SANDERS The next business is the appointment of a Committee on Nominations. I will appoint on this Committee Dr Wilkins, Dr Hubbard, Dr Chesley, Dr Woodman and Dr Perley

I will also appoint the committee which was to be chosen to act on Medical Relief, the Advisory Committee to the Welfare Department, Dr Graves, Dr Bowler and Dr Clarence O Coburn

We have now, I think, some further reports, and at this time, I will call for a report of the

Committee on Communications and Memorials, and will ask Dr Parsons to give this report.

DR PARSONS We have a communication from Dr Chase. It is the understanding of the Committee that gold medals are presented only to physicians who have been members of this Society for fifty years. Dr Chase has been a member since 1907 only, and it is the opinion of the Committee that Dr Chase is not eligible for the medal

A copy of a resolution adopted by the Chicago Medical Society, opposing the exploitation of drugs, remedies and so forth over the radio, was read

The New Hampshire Medical Society is opposed to the advertising, recommending, or in any way exploiting over the radio any preparations, remedies, medicines or appliances for the treatment of human ailments

SPEAKER SANDERS You have heard the report of the Committee on Memorials and Communications. What action shall we take, gentlemen?

DR WILKINS Unless some one wishes to take them up serially, I move that the recommendations be adopted

It was so voted

SPEAKER SANDERS I believe the Committee on Officers' Reports has some further reports to make at this time, and I will call upon Dr D G Smith for these reports

DR DEERING G SMITH

On the report of the Committee on Scientific Work, we recommend the acceptance of this report and the incorporation in the minutes of the Transactions of this Society

On the Report of the Committee on Medical Liability Insurance we recommend the acceptance of this report and the incorporation in the minutes

We further recommend that the name of the Advisory Committee on Jurisprudence be changed to the Committee on Conciliation

We recommend that Chapter 9 of the By Laws be re-written in conformity with the ideas embodied in Section 1 of this report

On the report of the Committee for the Control of Cancer we recommend the acceptance of this report and its incorporation in the minutes of the Transactions of this Society. We also recommend the continuance of this work, and the appropriation of Fifty Dollars asked for by the Committee

On the report of the New England Medical Council we recommend the acceptance of this report. On this matter action has already been taken by the House of Delegates

On the President's report, we recommend the acceptance of the report, and the incorporation of it in the minutes. We wish to thank Dr Graves for the tremendous amount of energy and time that he has spent in representing us with relation to the Relief Administration. We commend to the earnest consideration of the members of this Society

the various subjects so ably discussed by Dr Graves in his report

SPEAKER SANDERS You have heard the report of the Committee on Officers' Reports Is there any discussion?

DR LORD I would like to make a motion to this effect, that the report of the Committee on Officers' Reports be adopted, with the exception of that recommendation with regard to the Committee on Medical Jurisprudence

This motion was seconded by Dr Harry O Chesley

SPEAKER SANDERS It has been moved and seconded that the report of the Committee on Officers' Reports be approved and adopted, with the exception of that section pertaining to the change of name of the Advisory Committee on Medical Jurisprudence

The motion was carried

DR METCALF Dr Blood is here this morning, and I think if we have ten or fifteen minutes, it would be well to hear him

DR BLOOD The subject which I wish to bring up is the question of maternity and infancy I think it is vitally important to the State of New Hampshire, in the first place, and equally important to the physicians now and in the near future My interest in the matter is largely due to the formation of the New England Obstetrical and Gynecological Society in which we should have many more members from New Hampshire than we have

As a result of my connection with that society, I have been interested in what we are doing in this state It is hardly necessary to call to your attention the fact that there is no committee or section in this Society which is doing anything special along this line

Eight thousand mothers gave birth in this State, according to statistics About five hundred physicians attend those mothers, and they are distributed, of course, as we know, all over the state Some of them are back in the rural areas, where the physician arrives late or not at all, and some of them are in the cities It is rather interesting that the mortality is rather greater in the cities than it is in the rural areas It is also rather interesting that there is a great variation in the figures between the different cities, one city as high as 785 and another as low as 202 in the year 1932 By counties, it varies very much, too

The death rate in the first year of the child is also very high The only thing that is being done for this is being done through the Board of Health

It is my thought that this could be brought

about by the same method that we have in other specialties, to have a committee appointed to take charge of this, and work with the State Board of Health, that controls the state appropriation on this question

I believe that we are too small to have a section on this, but the committee would be much worth while

Discussion on this subject was then entered into by Dr Metcalf, Dr Lord and Dr Rublee

DR GEORGE C RUBLEE I wish to make a motion, that a committee of three or five, as the Chair advises, headed by Dr Blood, be appointed as a Maternity and Infancy Committee

This motion was seconded and was carried

SPEAKER SANDERS On motion duly made and seconded, I will now declare this meeting adjourned, until eight-thirty o'clock to morrow morning, standard time

Adjourned

WEDNESDAY, MAY 16

The House of Delegates convened for its third meeting at the Hotel Carpenter, Manchester, New Hampshire, on Wednesday morning, May 16, 1934, at eight-thirty o'clock.

The meeting was called to order by Dr Henry C Sanders, Jr, Vice Speaker

SPEAKER SANDERS The first business of the meeting this morning is to listen to a report of the Committee on Nominations

DR WILKINS Mr Speaker, Your Committee has met and considered all the vacancies to be filled and submits the following report

For President,

Frederic P Lord,
Benjamin W Baker,
Chancey Adams

For Vice-President,

Clifton S Abbott,
Charles F Nutter
Richard E Wilder

For Secretary Treasurer, to fill out the remaining year in Dr Sullivan's term, Carleton R. Metcalf
For Councilor for Cheshire County, A A Pratte,
for five years

For Councilor for Sullivan County, Emery M Fitch

Both are reappointments
Trustee, for three years, Thomas W Luce
Speaker of the House of Delegates, Henry C Sanders, Jr
Vice-Speaker of the House of Delegates James B Woodman

Necrologist, Clarence E Dunbar
Delegate to the A. M. A. 1934-35, Deering G Smith.
Alternate delegate 1934-35 Emery M Fitch
Delegates to the State Societies to be appointed by the Secretary, as has been the custom in the last few years

Committee for Scientific Work, Carleton R Metcalf, Frederick P Scribner and Richard W Roblin son

Public Relations, Public Policy and Legislation, Samuel T Ladd, John Dill, Charles Duncan, the President and Secretary Treasurer Ex Officiis

Publications, Carleton R Metcalf Henry H Amsden and Warren Butterfield

Tuberculosis Robert B Kerr, R. M. Deming A L Wallace

Mental and Social Hygiene, Charles H Dolloff Benjamin W Baker and Charles A. Weaver

Control of Cancer George C Wilkins, George F Dwinell and Howard N Kingsford

Lay Health Organizations, one member for five years Robert B Kerr

Medical Education in Hospitals one member for three years, Robert J Graves

The new Committee on Maternity and Infancy work, Robert O Blood, Benjamin P Burpee and Chester F McGill

SPEAKER SANDERS There is a quorum present, and now we will proceed to the election of officers. The first officer to be elected and voted for is the President

DR PAUL DYE I move you, Mr Speaker, that one ballot be cast by the Secretary for Frederic P Lord for President

This motion was seconded and was carried

SPEAKER SANDERS Dr Frederic P Lord, having one vote cast by the Secretary, is declared duly elected as President of the Society for the ensuing year

The next office to be filled is that of Vice-President. Please prepare your ballots for Vice-President. I will appoint Dr Dye and Dr Dube as tellers to check the ballots

(Ballots were then cast)

DR DYE I would like to report that there was a unanimous vote for Dr Abbott, thirteen ballots

SPEAKER SANDERS Then I declare Clifton S Abbott duly elected as Vice-President of this Society for the ensuing year

Our next business is to elect a Secretary-Treasurer to succeed Dr Dennis E Sullivan for the unexpired term. Dr Carleton R Metcalf is the Committee's nominee

DR DYE Mr Speaker, I move that one vote be cast for Dr Metcalf for Secretary-Treasurer

This motion was seconded and was carried

SPEAKER SANDERS We are now ready to proceed with the election of other officers

DR ROBERT J GRAVES I move that the Secretary be instructed to cast one ballot for the whole ticket

This motion was seconded and was carried

DR METCALF The Secretary has cast one ballot for the whole ticket

DR SANDERS Under the heading of new business, I am going to ask Dr Ladd to supplement his report of the Committee on Public Policy and Legislation.

DR SAMUEL T LADD Mr Speaker and Members of the House of Delegates—This Committee has functioned ever since I have been a member of the Committee, and we have tried to accomplish something, but with a flat failure. I believe that the duties of this Committee are so vast that the suggestions that I personally have are these. That the entire medical profession of the State must see to it that the program that we lay out for the coming year should be taken up by the individuals of our society and thereby go to our respective legislatures before election. In other words, the New Hampshire Medical Society must do what our honorable President suggested in his annual address. There must be more activity on the part of the medical society and if they want to accomplish any of these projects that will come up before the General Court, it will be necessary to do something about it.

DR GRAVES I believe very firmly that we should have our legislative program, so far as possible outlined within the next two months, three at the latest. We have always, before this, waited practically until after the legislature meets and the bills are in, before much of anything was done.

DR SAMUEL T LADD If I am going to serve on this Committee I am going to ask each and every one of you fellows in the counties and in the towns to see to it, if we put on a program, that you have carried it to your respective candidates irrespective of party affiliations. In that way, you are going to accomplish something. Otherwise, you are going to drift haphazardly, as we have been going for the last twenty-five years.

SPEAKER SANDERS There is a report that has been submitted on the Amendment to the Constitution and By-Laws. This Committee reports on the proposed amendment of Monday night.

DR METCALF The Committee on Amendments to the Constitution and By-Laws recommends

(1) That Chapter 1 Section 5 of the By-Laws be amended by adding the words 'or totally disabled' after the word age and by striking out certain words so that the section will read, Any physician who has been a member of this Society for a continuous term of fifteen years and who is either not less than sixty-five years of age or totally disabled, on the request of his country society, may be made an affiliate member by a majority vote of the House of Delegates. Affiliate members shall have the same rights and privileges as other members of the Society, but shall not be required to pay dues.

(2) That Chapter XI, Section 1, of the By Laws be amended by striking out the words "control, investing power and" in the second sentence, so that the sentence will read, "The distribution of its income shall be vested in a committee whose members shall consist of the Trustees of the Society, the President and the Secretary Treasurer"

The above section refers to the Benevolence Fund

SPEAKER SANDERS What action do you want to take on this report of the Committee on Amendments to the Constitution?

DR KEELEY I move that the report of the Committee on Amendments to the Constitution and By-Laws be accepted and adopted

This motion was seconded and was carried

DR H O SMITH A further recommendation of the Committee on Amendments to the Constitution and By-Laws is as follows

We recommend that no change be made in Chapter IX of the By Laws, relating to the choice and duties of the Advisory Committee on Jurisprudence

SPEAKER SANDERS You have heard the report of this Committee on Amendments to the Constitution and By-Laws What action will the House take on this report?

DR WILKINS I move that it be accepted and adopted

This motion was seconded and was carried

DR SANDERS I wonder if you have anything to say with regard to Resolutions on Dr Sullivan's death, to be drafted on behalf of the Society, Dr Lord

DR LORD You rather caught me unawares It is something that I have spoken of to some of the men I had felt that it was customary in organizations of this type to go on formal record in such a case as Dr Sullivan's death I feel very much that those things seem empty, very often, but I feel that we should go on record officially and make a proper resolution to be expressed on our records and sent to the members of his family, over and above what has been done so well by our Secretary in his reports and by our President I would be glad to hear what the others have to say about it I hadn't formulated anything further

DR METCALF I think it would be a very nice thing to do, and very acceptable to the members of his family Dr Graves has already

written something on it, and I wonder if he would be willing to elaborate that

DR GRAVES Dr Amsden has written the best obituary I have ever seen, and I move you, sir, that the House of Delegates request Dr Amsden to prepare a proper memorial and resolution, to be spread upon our records and forward a copy to Dr Sullivan's family

This motion was seconded by Dr Wilkins and Dr Metcalf and was carried

DR METCALF I would move you, Mr Speaker, that the thanks of the New Hampshire Medical Society be extended to the Manchester Medical Society, to the guests, the State Board of Health, the exhibitors and all those who have contributed to the success of this meeting

This motion was seconded and was carried

SPEAKER SANDERS The next business is the selection of the place for the next annual convention.

DR LORD I would like to make a motion, subject to being condemned by this organization, that the meeting be held at Manchester Apparently, it is the most popular place for our meeting I would move also that the date be left to the discretion of the Secretary or the President

This motion was seconded and was carried

DR PAUL DYE I move you, Mr Speaker, that we adjourn

This motion was seconded and was carried.
Adjourned at ten o'clock in the morning

OLD ELBOW INJURIES

Operations for Bony Block

BY FREDERIC JAY COTTON, M.D.†

IT is a matter of common experience that operations for cure of limitation of motion at the elbow are unsatisfactory. And such limitation of motion very often results from elbow fractures in adults to a distressing degree. In adults the problem is utterly different from that in children, in whom non-interference is the one best policy. After childhood one has nothing to hope from growth and adjustment, for time brings us nothing. And in many cases one hesitates to resort to the very useful operation of an arthroplasty, which involves at best some loss of power and stability.

The operations here described are among the very few that have proved really useful in cases demanding relief but not justifying arthroplasty. My knowledge of the two goes back to my army use of them in 1919. They are probably much older than that, but seem to be strangely little used.

Many cases of bony block to flexion and extension, even where there is considerable deformity of joint surface, are directly due to contact of the olecranon or coronoid process on bone. Not uncommonly, even without other bony deformity from fracture old elbow injuries show well-marked enlargement of the coronoid with or without evidence of direct injury, an enlargement directly obstructing flexion.

Operation No 1 This is simply the removal of the coronoid tip and as much more as seems wise. The route of access is in front, down the line separating the biceps and the supinator longus, and carried thence into the forearm. The first thing to do is to locate the radial nerve in the upper end of the wound. Once identified it is rolled out of the way, outward with the muscle. In the floor of the wound, that is the lower end, is the radial head and neck with the biceps insertion. With the arm flexed a bit, the biceps tendon can be pulled forward, giving direct access to the coronoid. Only the insertion of the brachialis anticus needs clearing away a bit, and much or little of the coronoid can be removed. The nerves and vessels to the inner side are hardly within dangerous reach.

Operation No 2 consists in the shortening of the olecranon. This is far more often called for, both because limitation of extension is more important than that of flexion and because impingement of the olecranon seems much more often the deciding factor in a block, and is more

often definitely overgrown*. The operation is facilitated by the fact, which one forgets, that the triceps tendon is not attached to the end of the olecranon, but essentially at its tip. Between the olecranon and the triceps tendon lies a considerable bursal space usually continuous with the subtricipital pouch and the joint.

The route of approach is from the outer side, with a curved incision back of the condyle and exposure of the articular junction of the external condyle and olecranon. Then one must determine how much is to come away. A triangle as sketched is usually about right and this can

CORONOID AND OLECRANON

Upper figure Overgrown tips of coronoid and olecranon processes

Lower figure Shows direction of cuts and approximate levels at which both bones can be cut away without damage to the joint. The cut in the olecranon is above the triceps tendon insertion.

*Most of the back end of the olecranon is covered by a bursa.

be spared without damage to joint or tendon insertion. It is very desirable to cut this triangle clear in one continuous cutting across with a medium-sized thin osteotome without ragged surfaces. That is all there is to the operation. No vessels have been cut, and no muscle save some anconeus fibres. One or two deep approximation sutures are used followed by interrupted skin sutures and pressure dressing as usual.

There is one point most important because merely removing the olecranon tip is not enough. The joint must be brought out to full extension and much force may be required. One may feel, and hear, the giving way of periarticular adhesions. Moreover, early and rather vigorous active motion, but short of pain production, is needful to keep what one has gained.

CASES

CASE I J F aged 26 gas plant worker seen for Dr. W H Bennett, of Taunton June 13 1932. Accident suffered on January 5, 1932, when he was caught

*This overgrowth irrespective of direct trauma, seems a reactionary sort of thing. There is no arthritis accompanying it merely an accretion of osteochondritic growth. Not uncommonly it shows up in reduced luxations with no fracture.

†Cotton Frederic Jay—For record and address of author see page 51, issue of April 12 1934.

in a conveyor belt. The injury to the elbow was the only serious damage.

The head of the radius was excised and he had much physiotherapy following the operation. As first seen he had elbow flexion ten degrees beyond the right angle, with no rotation in pronation, and in supination twenty degrees. Extension was good for forty-five degrees short of the straight line. X-rays showed the coronoid process long, the olecranon was much overgrown and very evidently limiting the range of extension. Operation June 21, 1932.

Typical operation: resection of at least $\frac{3}{4}$ " of the olecranon. The arm came down to almost 180° on the table. Under exercises his rotation improved beyond expectation and he was at work with no disability after three months, and examination showed $\frac{1}{2}$ normal supination, near normal pronation, extension passively to full 180° , a little less, actively. But active extension to 180° was noted, December 3, 1932.

CASE II. G. F., hospital attendant aged 38 seen November 2, 1933 for Dr. C. P. Hutchins of Syracuse. Injured four months previously. The elbow was dislocated in handling a patient but not recognized or treated. He is a small but powerful man. The right elbow was locked at a right angle. X-ray study showed a slight outward displacement bringing the ridge of the sigmoid cavity external instead of internal to the ridge between the trochlear and capitellar surfaces.

This displacement of about $\frac{3}{8}$ " brought the coronoid and the olecranon processes opposite the deep portion of the external condyle. That locked the joint in flexion and extension absolutely. Motion in rotation was not limited. Sensory loss in the third and fourth fingers clearly showed some damage to the ulnar nerve.

After four months any operative replacement of the joint would have meant "taking it all to pieces" with marked chance of having it freeze up again all together. Arthroplasty was particularly unattractive as this man's job needed a strong as well as a mobile joint. It was decided to try what clearing the olecranon blockade would do.

Operation November 3, 1933. Syracuse Memorial Hospital with Dr. Richard Farr. "Transplantation" of the ulnar nerve to the front was done first and proved not easy owing to the unexpectedly massive fibrous infiltrate throughout the whole region.

Then through the usual external incision, the olecranon was shortened, liberally.

The subtricipital pouch ("bursa") was opened and some heavy adhesions divided. The elbow was

then extended with cracking of heavy adhesions somewhere nearly 180° degrees, and flexion became practically normal. The joint motion was smooth with no jerks. Two days later there was no reaction, save a slight increase in anesthesia of the last two fingers, due to nerve handling. November 17, 1933 he was reported as soundly healed with motion in flexion 10 degrees beyond a right angle and extension through 30 degrees, to 120 degrees, with a range of 40 degrees a fortnight after operation, with exercises barely begun.

January 22, 1934 this man returned to full duty. Flexion to 60 degrees, extension to 147 degrees, pronation 80 degrees, supination 70 degrees. Slight ulnar hypoesthesia, persisted to that date.

CASE III. A. R., aged 30, a roofer, seen April 10 1933. Injury of August 19, 1931. He fell from staging sustaining compression fracture of the spine, and various other injuries. The remaining disability is of the right elbow only. He is a well-made muscular man. There is 50 degrees limitation of flexion. A fracture of the radial head does not now limit rotation. X-ray shows coronoid overgrown, but not impinging. The olecranon was overgrown, and in a film taken in a maximum extension the solid impact of the long olecranon tip in the olecranon fossa is unmistakable.

Operation Salem Hospital, October 8, 1933. A large wedge of the olecranon removed in the usual way. On manipulation after the operation the arm came out to full 180° degrees extension. Owing to delay in instituting exercises, extension was slow in returning, but January 24, 1934 he showed nearly full extension (15 degrees short) and in the x-ray only the regular partial reproduction of the excised bone. He is now ready for work.

CASE IV—(Inserted for contrast). J. O. B. aged 30, painter, seen October 27, 1933 for Dr. C. W. Harrison. The lesions were an injured spine and left wrist and left elbow in a fall of 30 feet, September 9, 1933. Essential disability was limited to elbow. No rotation, flexion to a little better than a right angle, extension fifty degrees short of the straight line. Preparations for removal of radial head and the typical olecranon wedge removal were made. The olecranon was definitely overgrown. At operation, November 10, 1933, the removal of the radial head completely cleared both rotation and extension so that there was no need of touching the olecranon. So the question of location of the block is not always easy. December 1, 1933. The patient has practically complete extension, and good rotation.

MORTALITY RATES

Telegraphic returns from 86 cities, with a total population of thirty-seven millions, for the week ending May 19 indicate a mortality rate of 11.3 as against a rate of 10.6 for the corresponding week of last year. The highest rate (21.5) appears for Wilmington, Del. and the lowest (5.3) for Flint, Mich. The highest infant mortality rate (25.1) appears for San Antonio, Texas and the lowest for Des Moines, Iowa. Erie Pa., Louisville, Ky., Lowell, Mass., Lynn, Mass., New Bedford, Mass., Oklahoma City, Oklahoma, Paterson, N. J., Salt Lake City, Utah and Yonkers, N. Y., which reported no infant mortality.

The annual rate for 86 cities is 12.4 for the twenty

weeks of 1934 as against a rate of 11.8 for the corresponding period of the previous year.

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS) FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS OF 1934 AND 1933

	Week ending		First 20 weeks	
	May 19, 1934	May 20, 1933	1934	1933
Total deaths —	152	135	3,128	2,759
Death rate —	21.2	18.8	21.8	19.2
Deaths due to accidents in city —	119	105	2,544	2,224
Death rate —	16.6	14.6	17.7	15.5

CASE 20241

PRESENTATION OF CASE

First admission A thirty-one year old American, a department manager in a paper box factory, entered for the first time a year before his final admission

Twenty-one months before admission the patient's mother noticed a slight swelling in the right side of his neck. He felt perfectly well at the time. From that time the swelling grew steadily larger except during two periods, the first four months before entry, when it became larger for a few days and then dropped to its usual size, and again a week and a half before entry, when it decreased in size, remaining small until admission. The swelling was always soft, painless, and never inflamed. He was forced to wear larger collars, changing them as the swelling grew. He had no hoarseness or difficulty in swallowing or breathing, and no other swellings elsewhere in his body. One month before admission he had a two week period of headaches localized between the temples and about the top of the head. These headaches were aggravated by noise, confusion, or any disagreeable incident. They were not present for the two weeks immediately before admission.

The family and marital histories are irrelevant. Twenty-one years before entry he broke his nose and since then had had some obstruction in his right nostril. Five years before entry while leaning over to pick up some papers he felt an agonizing pain in his right hip on standing up. This apparent back strain troubled him for about seven weeks, and since then his back had been weak. During the past ten days he had had a recurrence of this soreness in the right hip. He was slightly deaf in his left ear.

Physical examination showed a well nourished man apparently in good health except for a large lump in the right side of his neck. The right pupil was slightly smaller than the left. The right nostril was obstructed by a deviated septum. The teeth were ill kept and carious. The trachea and larynx were displaced to the left by a mass larger than a fist extending from the supraclavicular fossa to the parotid region and from the midline in front to the postauricular region behind on the right side of the neck.

There were firm, elastic, discrete, easily palpable masses from the size of a bean to that of a chestnut surrounding the larger mass. There were no other enlarged glands. The liver and spleen were not palpable. There was a two or three millimeter erosion on the anterior aspect of the scrotum. This had been present for approximately six weeks. The heart and lungs were negative. The blood pressure was 110/70 on the right side and 110/60 on the left.

The temperature was 99.6°, the pulse 90, the respiration 22.

Examination of the urine was negative. The blood showed a red cell count of 4,900,000, a hemoglobin of 80 per cent, a white cell count of 7,700, with 87 per cent polymorphonuclears, 1 per cent lymphocytes, 5 per cent large mononuclears, 2 per cent young polymorphonuclears. The platelets were normal in number. Examination of the stools was negative. The Hinton test was negative. The basal metabolic rate was plus 17.

X-ray examination of the chest showed clear lung fields except for an area of dullness involving the extreme right apex, interpreted as an overlying soft tissue mass, plainly visible in the neck.

The visiting man on service found in addition a slight pulse difference between the right and left sides, a palpable liver and spleen, and increased supracardiac dullness. Another white blood cell count six days after admission was 4,600, with a differential of 59 per cent polymorphonuclears, 29 per cent lymphocytes, 4 per cent large mononuclears, 7 per cent eosinophils and 1 per cent basophils.

A biopsy of one of the cervical glands was reported as lymphoblastoma, Hodgkin's type. X-ray treatment was begun. The patient was discharged on the twelfth day, to be followed in the X-ray Treatment Clinic.

History of interval Following an x-ray treatment after his discharge the swelling in his neck subsided, and for the next year he felt quite well. Eleven days before his second entry while walking beside a truck he suddenly turned his head for some reason and bumped it on the edge of the truck. He was stunned, but did not lose consciousness. The site of the injury was in the upper and front part of the temporal region. There was considerable localized edema and redness. Three hours after the accident he developed a generalized headache which gradually increased in severity and continued until admission. It was aggravated by any motion, interfered with his sleep, and was not relieved by pyramidon. The day before admission he entered the Emergency Ward. Skull films showed no evidence of fracture. The suture appeared quite widely separated and it seemed probable that the intracranial pressure was increased.

Second admission, a year after his previous discharge

Physical examination showed a well nourished man apparently in excellent health. There was slight stiffness and pain upon bending the neck. In both sides of the neck were many discrete soft non-tender glands from 5 to 15 centimeters in diameter. The spleen was palpable about one fingerbreadth down and upon deep inspiration the edge was sharp and firm. A complete neurologic examination was negative except for very severe headache.

The temperature was 103°, the pulse 110, the respiration 23. The blood pressure was 120/76.

Examination of the urine was negative. The blood showed a red cell count of 3,200,000, a hemoglobin of 70 per cent, a white cell count of 3,100, 86 per cent polymorphonuclears, 10 per cent lymphocytes, 4 per cent large mononuclears.

A lumbar puncture done in the Emergency Ward on the day before admission to the Neurological ward showed an initial pressure of 325. Pressure upon the jugulars showed no block. The spinal fluid was clear, colorless, and did not clot upon standing. The cell count showed 320 small round cells taken to be red cells. Some of them however had a small knob on one end suggesting that they might have been yeast cells. There were 28 white cells, 17 per cent lymphocytes. The total protein was 43, the sugar 316, the chlorides 708. Another lumbar puncture showed that these peculiar cells in the spinal fluid were definitely yeast cells and showed budding forms. A culture of the spinal fluid showed a good growth of yeast.

He continued to have spinal taps, each showing an increased cell count and yeast organisms. At one puncture 75 to 90 cubic centimeters of spinal fluid was removed over a period of two and a half hours. One-half normal saline was given intravenously. After eighty ounces of the fluid had been injected the headaches stopped. His temperature remained elevated and at times was picket fence in character, reaching as high as 104.5°. At admission he was irrational. On the forty-seventh day he developed bronchial breathing in the right chest. On the following day rales were heard all over the chest. The temperature was 103°. He gradually failed, became much weaker, and died approximately ten weeks after admission.

CLINICAL DISCUSSION

DR GEORGE W HOLMES. We have a long series of films on this patient, none of which is very interesting. The first observation was at the time of the first admission. I think you can see the large soft tissue mass in his neck and the area of dullness at the right apex which we interpreted as being due to pressure of the apex down from the mass in the neck. The glands in that region are not due to tuberculosis.

Then a series of films taken after treatment shows a disappearance of the mass in the soft tissues of the neck but not a complete disappearance of the shadow in the upper mediastinum and region of the apex. There are still no changes in the lung.

Then we have a slight increase in this shadow and a little later some disappearance in the shadow. It looks as if there was active disease in the glands in that region at that time.

The last film was taken three months before death. At that time there was still some widening of the upper mediastinum without any recurrence of the mass in the neck.

The skull films showed the characteristic blood vessel markings. The suture was not closed. In some of the films an area of diminished density is seen at this point. Another film shows a similar area at a different point. I do not know just how to interpret those. They may mean nothing, or they may mean localized areas of infiltration of lymphoma in the bone. They are not however characteristic.

A plate of the gastro-intestinal tract was negative.

DR JAMES B AYER. I have nothing to add, but I am interested in this relationship between yeast infection and lymphoblastoma. We certainly have yeast infection without lymphoblastoma, but the occurrence of the combination seems to be increasing. Is there anything in the pathologic field that correlates the two?

DR TRACY B MALLORY. No causal relationship has been proved. There are a number of scattered case reports and the combination has been very frequently observed.

DR FRANCIS T HUNTER. I might take this opportunity to protest about the usual dietetic description of lumps in the neck and various parts of the body. These are usually described as the size of a bean, and you cannot tell what kind of bean. It may be anything from a black eyed soy bean to a Mexican jumping bean. I think it is a pretty slovenly description. It is just as easy to say a centimeter or two, or something you can prove in court.

DR J H MEANS. There was an editorial on that in the New England Journal of Medicine or the American Medical Journal, we posted it on the bulletin board. I do not think that either that or Dr Hunter's complaint will alter the practice of comparing things to potatoes or anything else.

CLINICAL DIAGNOSES

Torula cerebrospinal meningitis
Lymphoblastoma

ANATOMIC DIAGNOSES

Torula meningitis with metastases to the kidney, adrenal and lungs
Lymphoblastoma, Hodgkin's type, involving spleen, bronchial and retroperitoneal glands

Acute bronchitis.
Pulmonary edema
Endocarditis, acute terminal, mitral
Otitis media, left

PATHOLOGIC DISCUSSION

DR. MALLORY The progress of science is shown by the fact that these small round bodies that looked like red cells were promptly recognized as yeast. The first case of torula meningitis in this hospital went totally unrecognized for a matter of days, during which counts of two, three and four thousand red cells were put down day after day in the record. I have forgotten whether the second was as promptly recognized as this one or not. The spinal fluid sometimes contains simply extraordinary numbers of yeast cells and there may be very little in the way of cellular reaction to them. That is borne out by the pathology in the brain in some of these cases. In our first case it was most striking. The entire brain presented a moth eaten appearance. There were great holes throughout the brain substance everywhere and in these holes nothing but masses of yeast without a sign of cellular reaction to them. To some degree that may have been postmortem overgrowth, but I feel fairly certain it could not have been entirely that, and the paucity of reaction is rather striking in many cases.

This happens to be the fifth case that I have seen of coincident torula infection and some form of lymphoblastoma. Four out of the five have been typical Hodgkin's disease. The fifth I saw the section from, prepared at the Mayo Clinic, and that undoubtedly was lymphosarcoma, not Hodgkin's, so that one can get it in either type. I had a chance two years ago to see a manuscript which so far as I know was not published, collecting some eighty odd cases of torula infection, and there were about a dozen in which torula and Hodgkin's were found together, so the coincidence is much too striking to be purely a matter of chance. It is not so close as the coincidence of tuberculosis and Hodgkin's, but it certainly approaches it.

In this man we found torula in two other spots besides the meninges. His adrenals contained several tiny little cysts and those are filled with yeast organisms practically without reaction. Scattered throughout his lung are milary lesions about the size of milary tubercles consisting of accumulations of monocytes, and in many of these are yeast cells.

The question of the portal of entry has never been settled and often nothing has been found at autopsy to suggest one. In this case with a lung infection it would seem possible that the lung was primary. On the other hand the distribution is so much like that of milary tuberculosis that it is quite possible that the lung is secondary.

It is interesting that in one of the other two

cases we had in the hospital lesions were also found in the adrenal.

DR. HOLMES Did you examine the skull?
DR. MALLORY I have no note on that, Dr. Holmes

CASE 20242

PRESENTATION OF CASE

A thirty year old unemployed American Negro saxophone player entered complaining of weakness and fever of six months' duration.

Approximately four years before entry the patient noticed a painless, colorless swelling under his left arm which gradually increased to the size of a hen's egg in a period of about one year. A short time after the appearance of the swelling he began to have frequent night sweats, fever, and occasional chills. He had no cough or hemoptysis. He lost some weight, but was able to continue his work as a saxophone player. There were no other swellings. Three years before admission he entered a New York hospital, where he remained for three and a half months, during which time he had a biopsy and x-ray treatment. He was discharged against advice. While in that hospital he was up and about, but had intermittent fever. The febrile cycles were about ten days at first and later lasted for about three weeks. According to the patient the biopsy report was Hodgkin's disease. The x-ray treatment that he received in New York was given to the left axilla, the abdomen and the back. For the next two years he lived at home, usually up and about, but at times he would have chills, fever and drenching night sweats. His appetite was good and he maintained his weight at 130 pounds. There was no diarrhea. He did not have steady work, but at times played the saxophone at a dance. Six months before entry he began to feel more tired and weak, and for the past two weeks had remained in bed. He had no chills, but he usually felt feverish and had frequent drenching night sweats. No swelling appeared. He became short of breath very easily. There was no cough, sputum or hemoptysis. Since his discharge from the New York hospital he had received no special treatment and no x-ray treatment.

His family and past histories are irrelevant.

Physical examination showed a well developed but cachectic colored man. There were a few small cervical glands. In the right axilla was a large firm non-tender gland two by two centimeters. There were occasional râles at the bases and bronchophony posteriorly over the scapular spaces. The heart was at the upper limits of normal in size. There was a blowing systolic murmur over the whole precordium and an early blowing diastolic murmur at the third left interspace. The blood pressure was 100/40. The pulse was collapsing in type. There was capil-

lary pulse and a positive Duroziez's sign. The abdomen was slightly distended. The spleen was felt two or three fingerbreadths down.

The temperature was 103.1°, the pulse 120, the respiration 36.

Examination of the urine showed a specific gravity of 1.018, a trace of albumin and an occasional hyalin cast. The blood showed a red cell count of 1,010,000, a hemoglobin of 20 per cent, a white cell count of 6,400, with 71 per cent polymorphonuclears. On smear most of the polymorphonuclears were young. The red cells showed marked achromia. Six normoblasts were seen. Examination of the stools was negative. A Hinton test was negative. A blood culture was negative.

Upon admission the patient was given a transfusion, following which the aortic diastolic murmur was inaudible. He became irrational. Four days later he was given another transfusion with a similar reaction. On the eleventh day a biopsy of the left axillary gland showed lymphoblastoma, Hodgkin's type. He failed very rapidly and died on the fourteenth day.

CLINICAL DIAGNOSIS

Hodgkin's disease

ANATOMIC DIAGNOSES

Hodgkin's disease involving the axillary, tracheal, retroperitoneal and mesenteric lymph nodes and the spleen

Acute miliary tuberculosis of the lungs, liver and kidney

Pulmonary tuberculosis, healed, left apex

Tuberculosis of tracheobronchial nodes, healed

Hypertrophy of the right kidney

Hydrothorax, bilateral

Ascites

Biopsy wound of left axilla

Appendectomy, healed

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY. The diagnosis of most cases of Hodgkin's disease of course is entirely unsettled until one has a biopsy and completely obvious afterwards, so that there is very little point in attempting differential diagnosis.

One point of interest, however, is why cases of Hodgkin's die and what they die of. It was for that reason that I picked out this case today. There was nothing in the clinical history to give anyone any lead and there was nothing peculiar noticed in gross at the autopsy either. When the microscopic sections came through, however, it was quite evident that we had two lesions side by side in many places and so intimately intermingled that in places no one could tell which was which. In all probability, however, Hodgkin's disease was not the immediate

cause of his death, but a fulminating miliary tuberculosis.

The only significant old focus of tuberculosis that we found was in his tracheal and bronchial glands.

The frequency with which tuberculosis and Hodgkin's occur in the same case of course has always been commented upon, but it has never been clear how to evaluate the association. If one looks hard enough for tuberculosis in the autopsy of any person above the age of twenty-five one can almost invariably find it. So that since this search for tuberculosis has been conducted with great enthusiasm I think it is not at all surprising that nearly invariably it is found in cases of Hodgkin's. On the other hand the number of cases in which acute tuberculosis is present is relatively much less striking. This is the second one in five years in the autopsy series here at the Massachusetts General Hospital.

The question always comes up as to whether x-ray treatment may or may not have influenced these cases unfavorably and possibly have caused the tuberculosis to progress more rapidly. How do you feel about that, Dr. Holmes?

DR GEORGE W. HOLMES. I should have said that the combination of tuberculosis and Hodgkin's is more common than you have stated it to be.

DR MALLORY. You think a significant degree of tuberculosis?

DR HOLMES. In the cases of Hodgkin's that do not do well under treatment we have found several that had evidence of tuberculosis, and I should think you would see more than you have.

DR MALLORY. One can get in pure Hodgkin's disease almost complete duplication of every picture one sees with tuberculosis, so that it might be hard to differentiate radiologically.

DR HOLMES. As to the effect of radiation on tuberculosis, I think with large doses one may cause tuberculous foci to light up, but the doses we generally use in Hodgkin's are not large enough to do that. In some cases that do not respond to the usual dose, a large dose may be given with breaking down of the glands. I am quite certain there are cases in which the glands have broken down and miliary tuberculosis has developed as a result. The possibility is well worth considering.

DR CHESTER M. JONES. How commonly do you see hepatic lesions in tuberculosis? It has struck me that they are very rarely reported here. I have talked with a man from Saranac who said it is very common. We see very little relatively, but as one reads in the textbooks it appears to be a very common finding. It seems to me it is uncommon in a general hospital.

DR MALLORY. If you have a terminal miliary tuberculosis the liver is almost always involved. A fair percentage of tuberculosis cases wind up with a miliary process, but aside from that I have never seen it here.

NEUROSYPHILIS

THE Annual Report of the Trustees of the Boston Psychopathic Hospital for 1933, in addition to giving a summary of the work of the hospital, which is of the highest character, also presents an important review of the treatment of neurosyphilis under the direction of Dr. Harry C. Solomon, Chief of the Department of Therapeutic Research. Treatment of syphilis of the central nervous system was started in this hospital in 1913 and it is interesting to recall with Dr. Solomon the various stages of the changes in therapeutics of neurosyphilis in the last twenty years.

The original work was stimulated by Swift and Ellis, who, in 1912, introduced intraspinal treatment with salvarsanized serum. Salvarsan had been brought to this country a few years before, and in the interval it was learned that this medication, so efficient against primary and secondary syphilis, was not especially efficacious in the treatment of general paresis and was

only valuable in a limited number of cases of tabes dorsalis. The type of treatment introduced by Swift and Ellis was used at the Psychopathic Hospital for about two years with what seemed to be a modicum of success. After an interruption by the War, this method was again taken up with the addition of arsphenamine to the serum and various other modifications. It was found that this method was successful in the treatment of cases of neurovascular syphilis and tabes dorsalis, but the effect on general paresis was not what one desired. Good results from the clinical standpoint were obtained in only ten per cent, with serological improvement in an even smaller percentage. The chief reason it was felt, for the failure of this type of treatment was that the serum did not reach the portion of the brain involved in the parietic disorder. In 1919 the Aver method of intrasternal puncture was invented and the introduction of intracasternal serum was taken up with enthusiasm. The rate of improvement by this method was about twice that of the old method and the serological results were also much better.

There was always, however, a search for improved methods and in 1923 one was found in a new arsenical preparation originated at the Rockefeller Institute called tryparsamide. This drug given intravenously proved to be markedly superior to the methods already mentioned and ultimately the use of tryparsamide, supplemented by arsphenamine bismuth and mercury, almost entirely replaced the other forms of treatment.

Within two years, however, namely in 1925, another and even more important method was introduced into the clinic. This was the treatment by inoculation malaria. It was found, moreover, that the combination of malaria and tryparsamide in some cases gave better results than either of these methods used independently. For a time in the search for a substitute, sodoku, or rat-bite fever, was tried. This was not found more satisfactory than malaria and has been discontinued. Lastly in 1931, diathermy and radiotherapy were added as a means of producing fever, to supplant that produced by malaria. It is too early to judge in regard to the value of this method.

Finally, Dr. Solomon summarizes the present treatment given to patients seen in his clinic. First he uses drugs, the main reliance being put upon tryparsamide, but with the use also of arsphenamine, bismuth and mercury, secondly, febrile treatment, using for this purpose malaria, typhoid vaccine, diathermy and the electric blanket. A combination of the above methods seems to give the best results and certainly improvement is now expected in well over fifty per cent of the cases, as compared with ten per cent twenty years ago.

The clinic has not been unmindful moreover,

of the families of these patients. Proper attention has been paid to the husbands or wives and the children of syphilitic parents. It is interesting to know that a new book is being prepared by the clinic, giving in detail the results of twenty years of study of this subject.

THE ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY

THE One Hundred and Fifty-Third Annual Meeting of the Massachusetts Medical Society at Worcester, June 4, 5 and 6, is a matter of history, with a record of seven hundred and eighty Fellows and sixty-seven guests in attendance.

Clinics were conducted at the several Worcester hospitals. These exercises provided a broad array of instructive material.

The six sections of the Society had excellent programs and were well attended.

Twelve scientific exhibits presented important features of public health activities, progress in dealing with special diseases and the social aspects of medicine. These were all of a high order and in conformity with a growing custom among state and national society meetings. Such exhibits are now regarded as among the most important features of information pertaining to scientific medicine and its social relations.

The selection of Dr. Warfield T. Longcope of Baltimore, Physician-in-Chief of Johns Hopkins Hospital, to deliver the Shattuck Lecture was fortunate, for he delivered a scientific exposition of "The Importance of Disturbances in Nutrition in Edematous States" which was appreciated by the Fellows. This address appears on page 1243 of this issue.

The business of the Council was conducted with dispatch and without any serious differences of opinion relating to the subjects in the agenda. The last draft of the By-Laws was accepted and adopted, and a Section of Dermatology and Syphilology added to the six hitherto functioning.

The commercial exhibits were as well arranged as possible with the resources of the hotel.

The success of the meeting depended in large measure on the well-planned details of administration by the State Society and the Worcester District committees which worked in harmonious cooperation, and great credit is due to the district committee in its untiring attention to details and especially arrangements for the entertainment of the visiting ladies.

The Annual Oration delivered by Dr. Lincoln Davis dealt with the trend of changes in the social structure of the country with the implication that the medical profession has the most definite responsibility in dealing with the uncertainties of the future and especially the

permanence of ideals and traditions of this nation. This inspiring address appears on page 1197 of the issue of June 7.

THE ANNUAL DINNER

The especially interesting social feature of the meeting was the Annual Dinner in the Hotel Bancroft on Tuesday evening with the visiting ladies as guests.

Dr. Robey provided a group of speakers who entertained the company with witty and appropriate preambles to instructive and stimulating addresses in response to felicitous introductions by the President.

His Honor, Mayor Mahoney of Worcester, cordially welcomed the Society and guests with the assurance of appreciation of the honor conferred in selecting his city for its Annual Meeting and his belief that the city will profit by the greater interest which will follow the instructive exercises of these three days. He invited the Society to come to Worcester again in the near future, and promised that the resources of the city would be available to insure successful and enjoyable meetings at all times.

The legal profession was represented by the Honorable James M. Morton, Jr., Judge of the United States Court of Appeals. His Honor contrasted the practice of law with that of medicine in an amusing way, showing that the slower and more elaborate approach of law to a definite question would never be appropriate in dealing with the emergencies faced by medicine. He explained that the police functions of the State required the controlling power of the courts to prevent abuses and that the law is the great safeguard against injustice. An illuminating explanation of the meaning of the Constitution and the Bill of Rights was presented, showing that the rights of the individual were protected by the Constitution as against the wishes and purposes of the majority until experience has demonstrated that the majority is right in its intention to change an existing order of society.

The Right Reverend Henry K. Sherrill, D.D., Episcopal Bishop of the Eastern Diocese of Massachusetts, in representing the clergy, paid a glowing tribute to the doctors of his earlier acquaintance with especial reference to the functions of the family physician. Having been associated with doctors in the World War, in his work at Base Hospital No. 6, and as a trustee of the Massachusetts General Hospital, he has come to feel that next to his church his greatest interest is in the hospital and that the great responsibility in both fields is the creation and maintenance of standards and the placing of men with the essential qualifications for the service required and the expectation of raising standards for the ministry which is also true.

of the medical profession Dr Sherrill throughout his address insisted on the cooperation of medicine and theology, for the spirit of mankind must rise above the material plane of existence. He feels that the average clergyman and the average physician working together can accomplish far more than either can accomplish working alone. In the most effective way he emphasized the growing understanding of the fact that there is no conflict in the respective fields of science and religion with impressive illustrations taken from his own experience in leading those afflicted with illness to an understanding of the great comfort and help in meeting physical and mental distress through confidence in the blessings of religious faith.

Dr Lewis Periy, Headmaster of Phillips Exeter Academy, in his preamble to the more serious message which he wished to present to the medical profession, led the audience through emotional responses to his real or imaginary experiences as only the gifted raconteur can do. After this display of wit he told of the real problems which one has to consider in dealing with the education of the adolescent boy and girl. He paid tribute to the earnest and ambitious spirit of the young people of the present day in our institutions of learning and showed clearly the importance of having a real understanding of the psychology of youth. He was confident that, given the right human material and the understanding and sympathetic instructor, we may trust the young people to solve the individual and national problems before the human race.

He discussed the problems of sports in our secondary schools and colleges and affirmed the belief that students need to play as well as to work and that competitive games have a definite place in the student's life.

Taken altogether, President Robey earned the enthusiastic gratitude of the Society, in providing a feast of reason and flow of soul which will long be remembered by those who were privileged to listen to these inspiring addresses.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

LONGCOPE, WARFIELD T. A.B., M.D. Johns Hopkins University School of Medicine 1901. Professor of Medicine, Johns Hopkins Medical School. Physician-in-Chief, Johns Hopkins Hospital. His subject is "The Importance of Disturbances in Nutrition in Edematous States." Page 1243. Address: Johns Hopkins Hospital, Baltimore, Maryland.

CHUTE, RICHARD A.B., M.D. Harvard University Medical School 1927. Assistant in

Urology, Massachusetts General Hospital. Visiting Urologist, St. Elizabeth's Hospital, Brighton. Consulting Urologist, Natick Hospital. His subject is "The Vital Importance of the Relation of Hyperparathyroidism to the Formation of Certain Urinary Calculi—and Its Remedy." Page 1251. Address: 352 Marlborough Street, Boston, Massachusetts.

BIEBERBACH, WALTER D. M.D. University of the South Medical Department, Tennessee, 1904. F.A.C.S. Urologist, Worcester City Hospital. His subject is "Pyelo-Ureteritis Cystica." Page 1254. Address: Worcester City Hospital, Worcester, Massachusetts.

HEPBURN, THOMAS N. A.B., A.M., M.D. Johns Hopkins University School of Medicine 1905. F.A.C.S. Urologist, Hartford Hospital. Consulting Urological Surgeon, New Britain General Hospital, New Britain. His subject is "Denervation and Displacement of the Ureter for Exaggerated Renal Colic with a Report of a New Case." Page 1255. Address: 179 Allyn Street, Hartford, Connecticut.

STONE, ERIC S.B., M.D. Harvard University Medical School 1918. F.A.C.S. Surgeon-in-Charge, Urological Service, Charles V. Chapin Hospital, Providence. Urological Consultant, Providence Lying-In Hospital, and South County Hospital. His subject is "Renal Sympathectomy. Report of Two Cases, Including One Fatality." Page 1257. Address: 199 Thayer Street, Providence, Rhode Island.

JONES, ARTHUR T. M.D. University and Bellevue Hospital Medical College 1896. F.A.C.S. of the families of these patients. Proper attention has been paid to the husbands or wives and the children of syphilitic parents. It is interesting to know that a new book is being prepared by the clinic, giving in detail the results of twenty years of study of this subject.

THE ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY

THE One Hundred and Fifty-Third Annual Meeting of the Massachusetts Medical Society at Worcester, June 4, 5 and 6, is a matter of history, with a record of seven hundred and eighty Fellows and sixty-seven guests in attendance.

Clinics were conducted at the several Worcester hospitals. These exercises provided a broad array of instructive material.

The six sections of the Society had excellent programs and were well attended.

Twelve scientific exhibits presented important features of public health activities, progress in dealing with special diseases and the social aspects of medicine. These were all of a high order and in conformity with a growing custom among state and national society meetings. Such exhibits are now regarded as among the most important features of information pertaining to scientific medicine and its social relations.

The selection of Dr. Warfield T. Longcope of Baltimore, Physician-in-Chief of Johns Hopkins Hospital, to deliver the Shattuck Lecture was fortunate, for he delivered a scientific exposition of "The Importance of Disturbances in Nutrition in Edematous States" which was appreciated by the Fellows. This address appears on page 1243 of this issue.

The business of the Council was conducted with dispatch and without any serious differences of opinion relating to the subjects in the agenda. The last draft of the By-Laws was accepted and adopted, and a Section of Dermatology and Syphilology added to the six hitherto functioning.

The commercial exhibits were as well arranged as possible with the resources of the hotel.

The success of the meeting depended in large measure on the well-planned details of administration by the State Society and the Worcester District committees which worked in harmonious cooperation, and great credit is due to the district committee in its untiring attention to details and especially arrangements for the entertainment of the visiting ladies.

The Annual Oration delivered by Dr. Lincoln Davis dealt with the trend of changes in the social structure of the country with the implication that the medical profession has the most definite responsibility in dealing with the uncertainties of the future and especially the

permanence of ideals and traditions of this nation. This inspiring address appears on page 1197 of the issue of June 7.

THE ANNUAL DINNER

The especially interesting social feature of the meeting was the Annual Dinner in the Hotel Bancroft on Tuesday evening with the visiting ladies as guests.

Dr. Robey provided a group of speakers who entertained the company with witty and appropriate preambles to instructive and stimulating addresses in response to felicitous introductions by the President.

His Honor, Mayor Mahoney of Worcester, cordially welcomed the Society and guests with the assurance of appreciation of the honor conferred in selecting his city for its Annual Meeting and his belief that the city will profit by the greater interest which will follow the instructive exercises of these three days. He invited the Society to come to Worcester again in the near future, and promised that the resources of the city would be available to insure successful and enjoyable meetings at all times.

The legal profession was represented by the Honorable James M. Morton, Jr., Judge of the United States Court of Appeals. His Honor contrasted the practice of law with that of medicine in an amusing way, showing that the slower and more elaborate approach of law to a definite question would never be appropriate in dealing with the emergencies faced by medicine. He explained that the police functions of the State required the controlling power of the courts to prevent abuses and that the law is the great safeguard against injustice. An illuminating explanation of the meaning of the Constitution and the Bill of Rights was presented, showing that the rights of the individual were protected by the Constitution as against the wishes and purposes of the majority until experience has demonstrated that the majority is right in its intention to change an existing order of society.

The Right Reverend Henry K. Sherrill, D.D., Episcopal Bishop of the Eastern Diocese of Massachusetts, in representing the clergy, paid a glowing tribute to the doctors of his earlier acquaintance with especial reference to the functions of the family physician. Having been associated with doctors in the World War, in his work at Base Hospital No. 6, and as a trustee of the Massachusetts General Hospital, he has come to feel that next to his church his greatest interest is in the hospital and that the great responsibility in both fields is the creation and maintenance of standards and the placing of men with the essential qualifications for the service required and the expectation of raising standards for the ministry which is also true.

of the medical profession Dr Sherrill throughout his address insisted on the cooperation of medicine and theology for the spirit of mankind must rise above the material plane of existence. MASSACHUSETTS LEGISLATIVE NOTES

H 1583 is an act providing for the insuring of the granite and foundry industries under the Workmen's Compensation Act and providing compensation for personal injuries from silicosis

This was reported by the Committee on Labor and Industries and awaits the action of the Legislature

S 162 which was designed to secure the registration of Chiropractors with power to practice in Massachusetts has been given leave to withdraw

This is one of the perennials and will blossom out next year in all probability

Massachusetts continues to adhere to a single standard for those who wish to practice the healing art.

MISCELLANY

MASSACHUSETTS PHYSICIANS ELECTED TO MEMBERSHIP IN THE AMERICAN PSYCHIATRIC ASSOCIATION

Dr. Moses Kaufman and Dr. Frederick Ledren were elected to membership in the American Psychiatric Association at the meeting held in New York in May, 1934

AN ENDORSEMENT OF DR. MAY'S BEHAVIOR IN TREATING DILLINGER

In a wireless to the *New York Times*, *The Lancet* upholds the Minneapolis physician recently fined and imprisoned for not informing authorities that he had treated John Dillinger, the bandit, and states 'A doctor does not cease to be a citizen. For Dr. Clayton May, however, there was only one question: Did Dillinger come to him for treatment trusting in his professional honor? The answer is obvious, and Dr. May's colleagues in every country will applaud his action in not betraying a professional trust'

We do not believe that the majority of the

physicians of this country are in agreement with the attitude taken by *The Lancet*

CONVICTS SUBMIT TO RESEARCH EXPERIMENTS

According to a report published in the *New York Times* two Colorado convicts volunteered for the experimental injection of tuberculosis bacilli employed to determine whether a certain serum will prevent the development of tuberculosis. Both of these men are serving life sentences. If they survive after the completion of the time required to demonstrate the effects of this treatment, the Governor will extend executive clemency. According to Dr. J. H. Corper of the National Jewish Hospital, Denver, Col., the duration of observation of the effects of the treatment will be from twelve to eighteen months.

One may question as to whether any convict may purchase freedom in this or any other way. If executive clemency is to be exercised, may not evidence of reformation of the convict's character be the deciding test? Even granting the importance of this contribution to medicine, is it reasonable to return to society a menace to human welfare? A person who has been made resistant to the tubercle bacillus may still be one of unsocial tendencies.

A STUDY OF RETARDED CHILDREN

In a study of 20,475 "retarded children" Dr. Neil A. Dayton, Director of the Division of Mental Deficiency of the Massachusetts Department of Mental Diseases in an address before the American Psychiatric Association reported his findings and conclusions of conditions existing in family groups. He found that in larger families the children are superior in arithmetic, obedience and sociability, but they frequently include such "personality and behavior characteristics" as lying, stubbornness, suggestibility and quarrelsomeness.

In smaller families the children show more of a tendency to seclusiveness and egotism. They are also more inclined to steal, and are more selfish and over affectionate, according to the report.

It was explained that the study was made of normal families except for one defective child in each.

RECENT DEATHS

NILES—JOHN OTIS GARFIELD NILES, M.D., of Everett, Massachusetts, born in 1880, died while swimming near his summer home on Plum Island, June 5. It is supposed that he suffered a heart attack. He was educated in the schools of Somerville, and the Cambridge Latin School. He graduated from Harvard College and in 1914, from Harvard Medical School. Dr. Niles practiced successfully in Everett, and had served as city physician. He was a Fellow of the Massachusetts Medical Society, and the American Medical Association, a member of the Harvard Club, and was an accomplished musician. He is survived by his widow, Mrs. Annie Louise

(Vaughan) Niles a daughter, Mrs Irene V Chandler of Hartford, Connecticut, and two sons Otis I Niles and Alvah N Niles

ROBINSON—ERNEST FREDERICK ROBINSON, M D of Auburndale Massachusetts, died at his home June 6 1934 He was born in 1870, and graduated in medicine from the University of Buffalo School of Medicine in 1891

He retired from active practice several years ago He is survived by his widow his mother, a brother and a daughter

OBER—HERBERT CARROLL OBER M D, of Newt Mass died June 10, 1934 at the Winchester Hospital of which he was staff physician

He was born in Amherst, Mass in 1886, the son of Dr Fred A. Ober and Mrs Alice J Ober He studied dentistry at the Harvard Dental School and graduated in medicine from the Boston University School of Medicine in 1916

Dr Ober joined the Massachusetts Medical Society in 1921 and had served on the Staff of the Memorial Hospitals He had recently served as F E R A. physician at Camp Curtis Wild in Westfield

He is survived by his mother

MACNAUGHTON—PETER J MACNAUGHTON M D a retired lieutenant colonel in the United States Army medical corps, died at his home in Wenham Massachusetts, June 8, 1934, aged 66

He was born at Lake Linden Michigan and graduated in medicine from the University of Michigan He began army service during the Spanish American War, and served in the World War He was later assigned to the army base in Boston and was retired in 1931 He is survived by his widow Mrs Ethel MacNaughton, and a son W Rossiter MacNaughton, both of Wenham

REPORTS AND NOTICES OF MEETINGS

PLYMOUTH DISTRICT MEDICAL SOCIETY

A stated meeting of the Plymouth District Medical Society was held at Lakeville Sanatorium, April 25, 1934 Dr Henry D Chadwick, Commissioner of Health of Massachusetts, was the guest speaker of the evening His address related to the control of some of the communicable diseases He said in part, that in 1923 there were 9000 cases of diphtheria with 500 deaths in the state while in 1933 the morbidity had fallen to 540 cases with only 53 deaths This reduction may be attributed largely to the immunization of children It is best to immunize between the age of six months and one year, as it is during this period that the passive immunity present at birth begins to wane By early immunization, cases in children of preschool age may be prevented Toxoid, which contains no horse serum, is advised for children under six years of age toxin antitoxin after this age Both products are available through the State Department of Health.

The use of pneumococcus serum for the treatment of lobar pneumonia will remain in the hands of a group of physicians fully acquainted with the technique of administration. At present it is of value only in Type I and Type II lobar pneumonia and must be used within the first four days of the disease It must still be considered an experimental therapeutic agent. The Commonwealth or Harkness fund finances this work, at a cost of seventy five to eighty dollars per patient, whereas the serum purchased from a private firm would cost between two and three hundred dollars

Measles mortality has fallen to 0.16 per cent, perhaps because of better home care Dr McKhann of the Children's Hospital in Boston has shown that placental extract contains a substance that will give a passive immunity to an exposed child if administered within five days after exposure After the seventh day it will modify the measles and produce a mild abortive attack The latter procedure is the choice in children over six years of age as completely preventing the disease leaves the child susceptible to subsequent infection

REPORTS AND NOTICES OF MEETINGS

PLYMOUTH DISTRICT MEDICAL SOCIETY

A stated meeting of the Plymouth District Medical Society was held at Lakeville Sanatorium, April 25, 1934 Dr Henry D Chadwick, Commissioner of Health of Massachusetts was the guest speaker of the evening His address related to the control of some of the communicable diseases He said in part, that in 1923 there were 9000 cases of diphtheria with 500 deaths in the state while in 1933 the morbidity had fallen to 540 cases with only 53 deaths This reduction may be attributed largely to the immunization of children It is best to immunize between the age of six months and one year, as it is during this period that the passive immunity present at birth begins to wane By early immunization, cases in children of preschool age may be prevented Toxoid, which contains no horse serum, is advised for children under six years of age toxin antitoxin after this age Both products are available through the State Department of Health

The use of pneumococcus serum for the treatment of lobar pneumonia will remain in the hands of a group of physicians fully acquainted with the technique of administration At present it is of value only in Type I and Type II lobar pneumonia and must be used within the first four days of the disease It must still be considered an experimental therapeutic agent The Commonwealth or Harkness fund finances this work, at a cost of seventy-five to eighty dollars per patient, whereas the serum purchased from a private firm would cost between two and three hundred dollars

Measles mortality has fallen to 0.16 per cent, perhaps because of better home care Dr McKhann of the Children's Hospital in Boston has shown that placental extract contains a substance that will give a passive immunity to an exposed child if administered within five days after exposure After the seventh day it will modify the measles and produce a mild abortive attack The latter procedure is the choice in children over six years of age as completely preventing the disease leaves the child susceptible to subsequent infection

Temporary immunity to scarlet fever may be obtained with convalescent serum which, however, is too expensive for general use. Active immunization with toxoid is still in an experimental stage but has been found efficacious in controlling outbreaks in several institutions. No case of smallpox has been reported in the state for the past two years.

The decreased incidence of typhoid fever is one of the triumphs of sanitation and preventive medicine. While the water supply in several parts of the state is still not ideal, the great majority of recent cases have been traced to typhoid carriers. With the decrease in cases there will be fewer carriers and a further reduction in typhoid morbidity may be expected.

Tuberculosis remains the most important infectious disease and both for the sake of the patient and the community early diagnosis is imperative. This is often difficult by any physical examination, especially so in children, and in all suspicious cases an x-ray examination of the chest is indicated. Approximately one out of every 100 with a positive von Pirquet test can be shown to have pulmonary tuberculosis. The possibility of an undiagnosed adult case in the household as a source of infection of the child is very great.

ALUMNI ASSOCIATION OF BOSTON UNIVERSITY SCHOOL OF MEDICINE

At the annual meeting of the Alumni of the Boston University School of Medicine, Dr. Harold L. Babcock was elected president, Dr. Helmuth Ulrich vice-president, Dr. Louis C. Howard, second vice president, Dr. Rudolph Jacoby, secretary, and Dr. Harold W. Ripley, treasurer.

Speakers at the dinner, which was a feature of the occasion, included Dr. Harold L. Leland, Dr. Alexander S. Begg, dean of the school, Dr. H. L. Babcock, and Dr. Daniel L. Marsh, president of Boston University.

NEW ENGLAND SURGICAL SOCIETY

The 1934 Meeting of the New England Surgical Society will be held at Burlington, Vermont, Friday and Saturday, September 28 and 29.

JOHN M. BIRNIE, M.D., Secretary

FIRST INTERNATIONAL CONGRESS OF ELECTRO-RADIO-BIOLOGY

The International Society of Radio-Biology announces that His Excellency Benito Mussolini on account of the favorable advice of the National Council of Research, approved the initiative to call an International Congress of Electro-Radio-Biology. This First International Congress of Electro-Radio-Biology will take place from September 10-15, 1934, in the Doges Palace at Venice.

The Congress will be presided over by His Excellency the Marquis Guglielmo Marconi, President of the Royal Academy of Italy, President of the Na-

tional Council of Research, State-Senator and by His Excellency, Count Giuseppe Volpi di Misurata, State-Minister, State-Senator.

The object of this Congress is to invite for a discussion Physicists, Chemists, Biologists, Naturalists, and Physicians, on biological actions of all radiations, in order to coordinate the respective investigations.

The biologist will learn from the physicist the theoretic and experimental basis of the physical researches on the vibratory and corpuscular phenomena. The physicist and the physico-chemist will learn from the biologist what are the influences that these phenomena have on cellular elements, complex tissues and on organic processes.

Moreover, the organizers of the congress hope to determine a new radio-biological tendency of many present physical and biological investigations.

The Congress intends to study the chemical and biological phenomena in respect to radiations.

For further information the request may be made to the General Secretary of the Congress, Dr. Glorindo Protti, S. Gregorio 173, Venice (Italy).

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

June 19—Lawrence Cancer Clinic. See page 1299.

July 24-31—The IVth International Congress of Radiology will be held in Zurich under the presidency of Professor H. R. Schnitz. General Secretary Dr. H. E. Walther, Gloriastrasse 14, Zurich.

August 18-September 30—Medical Study Trip to Hungary. See page 975. Issue of May 10.

September 3-6—American Public Health Association, at Pasadena, California. Dr. J. D. Dunshee, Chairman. Local Committee on Arrangements.

September 4, 5-6—International Union Against Tuberculosis. For information address the National Tuberculosis Association, 450 Seventh Avenue, New York City.

September 10, 11, 12, and 13—American Congress on Physical Therapy will meet in Philadelphia at the Bellevue Stratford. For details write American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Illinois.

September 10-15—First International Congress of Electro-Radio-Biology. See notice elsewhere on this page.

September 28-29—New England Surgical Society. See notice elsewhere on this page.

October 22-November 2—1934 Graduate Fortnight of the New York Academy of Medicine. See page 1240. Issue of June 7.

October 31-November 2—Massachusetts State Nurses Association Hotel Statler, Boston. For information write Miss Helene G. Lee, R.N., 420 Boylston Street, Boston.

BOOKS RECEIVED FOR REVIEW

Corrective Physical Education. By Josephine Langworthy Rathbone. 292 pp. Philadelphia: W. B. Saunders Company. \$2.50.

L'Eczéma du Nourrisson. Par les docteurs M. Péhu et R. Anagnier. 174 pp. Paris: Gauthier Villars, Editeur, 1934. 25 fr.

Urinary Analysis and Diagnosis. By microscopical and chemical examination. By Louis Heitzmann. Sixth Revised Edition. 385 pp. Baltimore: William Wood and Company. \$5.00.

The Principles of Gynecology. A textbook for students and practitioners. By William Blair Bell. Fourth Edition. 848 pp. Baltimore: William Wood and Company. \$10.00.

Genealogy of Sex. Sex in its myriad forms, from the one-celled animal to the human being. By Curt Thesing. Translated from the German by Eden and Cedar Paul. 320 pp. New York: Emerson Books Inc. \$5.00

New and Nonofficial Remedies, 1933. Containing descriptions of the articles which stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1933. 510 pp. Chicago: American Medical Association Press. \$1.50

Diseases Peculiar to Civilized Man. Clinical management and surgical treatment. By George Crlie. Edited by Amy Rowland. 427 pp. New York: The Macmillan Company, 1934. \$5.00

Obstetric Medicine. The diagnosis and management of the commoner diseases in relation to pregnancy. Edited by Fred L. Adair and Edward J. Stieglitz. 743 pp. Philadelphia: Lea & Febiger. \$8.00

The Chemistry of the Hormones. By Benjamin Harrow and Carl P. Sherwin. 227 pp. Baltimore: The Williams & Wilkins Company. \$2.50

BOOK REVIEWS

Hypertension and Nephritis. By Arthur M. Fishberg. Third Edition thoroughly revised. 668 pp. Philadelphia: Lea & Febiger. \$6.50

This book maintains its place in the field of medicine as the most complete work offered to the profession. It is a reference book, a practical manual, a summary of present day ideas of hypertension and nephritis, and best of all it is something which can be used by anyone interested in this field.

The tests for kidney function are described clearly. There are five tests given to determine concentration and dilution, the whys and wherefores are stated definitely.

The sections on Uremia, Hypertension, Arteriosclerosis, and Essential Hypertension are well done. The psychical aspect of chronic disease is presented in a most understanding way, and particularly so in Essential Hypertension.

This book is one to be owned and not lent. It is an outstanding work of first quality presenting Hypertension and Nephritis thoroughly and practically.

Japanese Medicine. By Y. Fujikawa. Translated by John Ruhräh. 114 pp. New York: Paul B. Hoeber Inc. \$1.50

This little book is a translation from the German of a short history of Japanese medicine written in 1911. It has been brought up to date by a second Japanese author and skillfully translated by Dr. Ruhräh of Baltimore. The various chapters cover the subject from the time of antiquity throughout the ages to the more recent history of Japanese medicine already familiar to most of the medical world. The facts appear to be well presented and one is surprised at the number of important advances made by Japanese workers. As an appendix

there is a chronological table of Japanese medicine and the book is well indexed. Although perhaps not up to the high standard set by previous volumes in this series, this book should find a place in the libraries of all medical historians.

Transactions of the American Gynecological Society. Volume 58, 1933. Edited by Otto H. Schwarz. 318 pp. St. Louis: C. V. Mosby Company, 1934.

The bulk of the Transactions edited by Otto Schwarz, is made up of three papers on the Toxemia of Pregnancy and five on Cancer of the Uterus. There is a discussion of the occipitoposterior position, based on a series of 657 cases describing the internal rotation of the head to anterior position in the opposite oblique diameter, with forceps above the brim of the pelvis. The most arresting paper is that by Lewis on the Effects of Theelin in Gonorrheal Vaginitis in Children. Specific vaginitis in little girls is a notoriously unsatisfactory condition from the standpoint of treatment and results. Lewis briefly reports eight cases treated only by injections of this hormone with astounding results. Follow-up examinations several months later showed a gratifying percentage of apparent cures. The volume contains an obituary note on William Lambert Richardson, beloved of hundreds of Harvard graduates of the nineties and early nineteen hundreds.

The Pocket Anatomy. By C. H. Fagge. Ninth Edition. Students Aids Series. 333 pp. Baltimore: William Wood and Company. \$2.00

Of the much abused and maligned group of so-called Quiz compends, Fagge's is one of the oldest and best. Published originally by George Brown, M.R.C.S. in 1876 as 'Aids to Anatomy', this book was reissued under its present title in 1881 and its first four editions were supervised by Edward Cotterell, M.D. The present editor began his work with the fifth edition in 1901 and in this present ninth edition has brought the publication to date. For the first time, there is used in this edition a new English terminology approved by the Anatomical Society of Great Britain and Ireland, which appears to be a happy compromise between the B.N.A. and the older vernacular nomenclature. A glossary tabulates the most notable changes from the terminology used in the eighth edition. The section on the brain has been revised in the light of recent physiologic investigations on the Central Nervous System, and the surgical anatomy of the Autonomic Nerve System has been revised in the light of recent progress in this department. Naturally such a work as 'The Pocket Anatomy' cannot, and is not intended to, be exhaustive. Apparently the mammary glands are among the more important of its major and perhaps in evitable omissions. Such a work is, of course, not designed to replace the standard systematic textbooks of Anatomy. It has, however, a definite place of value as a manual or syllabus for purposes of study and review.

Die Digitalisbehandlung Von Prof Dr Ernst Edens
Second Edition 154 pp Berlin and Vienna
Urban und Schwarzenberg, 1934

This extremely instructive monograph crystallizes a vast personal experience with the use of digitalis. It deals with its use in conditions associated both with a regular and with an irregular heart. The author considers the action of digitalis from the point of view of its "diastolic" (slowing of the heart) and "systolic" effects (alleviation of signs of decompensation without slowing of heart). He gives as the indications (sine qua non) for the use of digitalis, cardiac hypertrophy plus evidence of cardiac failure. As in most continental works, emphasis is placed upon the advantages of strophanthin over digitalis in its "systolic" effects. Excellent discussions are given of auricular fibrillation, pulsus alternans and the prognostic significance of bigeminy. The impossibility of predicting just what digitalis will do in the individual case and the need for cautious experimentation are stressed. The author shows how the drug may inhibit certain conditions such as extrasystoles, auricular fibrillation or pulsus alternans in one case, which it might tend to produce in another. A statistical analysis of digitalis effects, although of no value in predicting the response in a given case, but giving a clue as to the expected result, would enhance the value of this study. Without this, the unusual and atypical effects assumed an exaggerated importance. The volume, which offers an excellent résumé of practical cardiac pharmacodynamics, is written in clear, concise and entirely readable German and can be highly recommended.

The Queen Charlotte's Textbook of Obstetrics By Aleck W Bourne and others Third Edition 679 pp Baltimore William Wood and Company \$6 00

Ever since the publication of its first edition, in 1927, the Queen Charlotte's Textbook of Obstetrics has represented the views and methods practiced by those constituting the Staff of Queen Charlotte's Maternity Hospital. This third edition, consequent upon subsequent changes in the Hospital Staff, brings to the Board of Editors of this volume Drs Bourne, Davies, Rivett, Phillips, Lane-Roberts, and Williams, the last of whom has replaced Dr Bannister. Some portions of this edition have been largely rewritten, including the chapters on Mal Presentation and Anesthesia. In other parts extensive revisions have been made and new procedures and techniques, such as the Zondek Aschheim Test and the Kleiland Forceps have been added. Twenty new illustrations have been added bringing the total to 301 text figures with four colored plates. Queen Charlotte's Hospital is to British Obstetrics what the Rotunda is to Irish and this volume, which has become a standard among obstetric textbooks, is also of value to the discriminating student of comparative obstetrics, as fairly representing the practice and teaching of the members of this Hospital Staff.

Traité de Physiologie Tome I. By Prof G E Roger and Prof Léon Binet. 1140 pp Paris Masson et Cie 145 fr

This volume, covering general physiology, is the eighth to appear in the system of physiology edited by Roger and Binet. It is an interesting presentation of a wide range of material. Roger contributes a rather general summary of the properties of living matter and touches briefly on the vitamins, enzymes, and hormones in relation to life, and ends with an interesting discussion of senescence and death.

Policard contributes a short section on the general aspects of cellular physiology. Verne presents a section on tissue culture, which is short but excellent.

The discussion of the vitamins is decidedly disappointing and far from up to date.

The most ambitious section of the volume is that by Blanchetiere discussing the constituents of protoplasm, the constituents of a nucleus, of connective tissue, and the physiological rôle of the mineral elements. Perhaps the most interesting section to practicing physicians is that contributed by Lacasagne on the action of x rays and radioactive substances on living matter. This section, while short, is excellently done and written in a highly interesting style, perhaps a bit too speculative but nevertheless thought provoking. A section on ferments by Ambard and one on venins by Arthus conclude the volume.

A serious inconvenience is the absence of an index.

Text Book of Gynecology for Students and Practitioners By James Young Third Edition 411 pp New York The Macmillan Company \$3 75

This is the third edition of a book by a master of gynecology. It is, in fact, an up-to-date textbook on the subject. It tells everything that a medical student should know on which to base his later clinical experience and tells it all admirably in simple, easily understood English, accompanied by satisfactory illustrations which do not fail to explain and illustrate the subjects dealt with.

From a teacher's standpoint, it is particularly valuable because it emphasizes the description of gynecological conditions without going into too great detail in regard to surgical operations, although the main principles involved in the surgical cure of gynecological conditions is described.

Especially to be commended are the chapters on menstruation and a description of the hormones of the ovary and the action of the anterior lobe of the pituitary gland. An easily understood illustration showing the time relation between ovarian and uterine cycles with the increase and drop of estrin and progesterin is worth looking at.

Dr Young's book can be recommended to those who wish to review the subject and to students who are beginning it.

NUMBER 25

ARTIFICIAL MENSTRUATION*

Effect of Female Sex Hormones In Amenorrhea

BY JOHN ROCK M.D.†

THE cyclic changes occurring in the endometrium of the normal mature human female have been described with gratifying agreement by many investigators and the temporal correlation of these changes with those occurring in the follicular apparatus of the ovary convincingly demonstrated (Schroder, Novak, Bartelmez, O'Leary). The actual causal relationship of similar changes in the endometrium and ovaries of various other lower mammals as well as the relationship of changes almost identical with those of the human being, in the endometrium and ovaries of monkeys has been equally well demonstrated by several biologists (Allen, Hartman, Correr, etc.). These men have gone even farther and have shown that certain of the various changes occurring in the endometrium of laboratory mammals are actually the effects of the specific hormones, first of the developing follicle, folliculin, or estrin or theelin, and secondly of the corpus luteum corporin, or progestin. It was fair to assume then, that the same correlated changes in the human ovary and endometrium were cause and effect phenomena attributable to the same hormones. Incontrovertible demonstration of this causal relationship in human beings has been impossible for obvious reasons, but a few clinical reports suffice to justify the assumption.

Let us first review the correlated changes occurring in the endometrium and ovaries, and later consider the evidence of a causal relationship between them.

Immediately after the menstrual flow has begun and while it ensues (Bartelmez) regeneration of the defects made in the mucosa by separation of fragments is rapidly carried on, probably to a large extent by the embryonic histocytes of the stroma (Papanicolaou, Bain) and also by the glandular epithelium (Schroder, Novak, O'Leary) so that almost as soon as menstruation is over the uterine cavity is lined by a thin mucosa about 2 mm in diameter, consisting of simple straight glands and dense lightly vascularized stroma. The epithelial cells lining the cavity of the uterus as well as that of the glands are barely columnar, the nucleus is near the middle and the volume of the nucleus is to that

of the cell as 1:2.2 (O'Leary). The stroma cells are closely packed, the nuclei small, and the cytoplasm almost too slight to be seen, except in the occasional connective tissue cell. Wandering cells are few. At this stage the corpus luteum of the preceding ovulation is rapidly regressing and the new follicles are beginning to grow. Comparatively small amounts of folliculin are thus available.

As the dominant follicle acquires supremacy and grows rapidly during the next several days, larger amounts of folliculin are elaborated. After the first week mitotic figures are frequent in glandular epithelium. This then, is the proliferative phase. The cells of the surface and glandular epithelium become higher. By the eleventh day the nuclei have approached the base of the cells and have increased in size with the cytoplasm and the ratio of nuclear to the cytoplasmic mass is roughly as 1:2.9, which is much the same as at the beginning of this phase. The nucleus comprises 34 per cent of the cell volume although the cells are taller and narrower. The glands, because of the invagination, are necessarily longer and are straight. The stroma is less dense but there is no great change in the stroma cells at first. As the amount of folliculin is increased by the growing follicle which during this phase ruptures with ovulation and continues on to form the corpus luteum, the proliferation of the existing glands progresses, new ones grow upward from those of the basal layer and some of the older ones sprout branches (O'Leary). The glands are thus more numerous and close together. The stroma becomes even less dense, possibly with edema, certainly with some kind of fluid. Its vascularity increases, or at least its vessels are more noticeable, and its cells swell, so that not only are the nuclei larger but in most cells the cytoplasm as well has increased to easily discernible proportions. The cytoplasm of the epithelial cells has almost doubled in volume, so the nucleus, increasing less, only takes up 27 per cent of the cell volume, a ratio of 1:3.6. The wandering cells increase in number, and toward the end of this phase include among them many free red corpuscles singly and in groups of varying size. Necessarily the thickness of the mucosa has increased, roughly another centimeter by the end of the third week (Bain).

From the Free Hospital for Women, Brookline, Mass.
May 11 1934

†Rock, John—Surgeon to Out Patients, Free Hospital for Women, Brookline. For record and address of author see "This Week's Issue" page 1344.

Toward the end of this, the regenerative phase though the corpus luteum has begun to form, the amount of progesterin is small while the production of folliculin is at its height. During the last week of the normal cycle, however, the corpus luteum is in the ascendancy, the proportion of progesterin increases, and at the same time the endometrium noticeably changes. This is the secretory or functional phase. The epithelial cells which at the beginning of this phase have acquired glycogen open up and disgorge their contents into the gland lumen. As a result their surface is frayed and they gradually approach the cuboidal shape. The nucleus is somewhat larger and takes up almost one-half the cell again. The glands, increased in number and lying close together, become very tortuous folding in and out or twisting on their long axes so that a cross-section shows many papillary projections into the lumina. They are dilated to several times their original diameter. The stroma is now widely distended with fluid and in the upper portion, especially, filled with extravasated blood. The arterioles are many, large, and engorged. In many places, the histiocytes of the stroma have increased in size, the nuclei having swollen some, but the cytoplasm more, so that many have now become large enough to be termed predecidual cells.

After two or three days of approximately this condition the mucosa goes on to form decidua if impregnation has occurred and the corpus luteum has grown, regressed, and contracted, if failure of impregnation allows regression of the corpus luteum. Such is normal menstruation.

The appearance of cyclic sanguineous flow, however, at least in certain monkeys, is no assurance that both the proliferative and secretory phases of endometrial activity, described above, have occurred. Hartman and others have shown that in the absence of the corpus luteum there is a cyclic bloody discharge in monkeys, and Corner has produced this in spayed animals by the use of theelin alone. The studies reported here were undertaken in part to test the significance of these findings in clinical gynecology.

Folliculin (in the form of Progynon-B) alone, and the same folliculin followed by corporin in the form of Proluton-B* were given to five patients with amenorrhea of at least a year's duration, in this attempt to study the normal influence of the follicular apparatus on the human endometrium. All medication was given deep in the gluteal muscles. Apparently normal menstruation promptly ensued in four cases and slight staining in the fifth. Biopsies of the endometrium were obtained before, during and after the treatment in one case, and before and after in three others, in an effort to identify the specific effects of each hormone. This was

done by a modified Klinger and Burch suction technique. A simple open tube was used, 3 mm. in diameter with a curved, sharpened and notched hook over the uterine end made by prolonging and bending over one-quarter of the wall of the tube to within 3 mm. of the opposite side, leaving the lateral walls open. This was attached by a short rubber connection to a tight glass syringe. A cock was placed in the proximal end of the tube to insure maintenance of negative pressure in it during its withdrawal from the uterus after the syringe was removed. The contents stripped from the uterus by gentle stroking of the curette and sucked into the tube by the syringe, were then washed into a bottle with 10 per cent formalin. This procedure, simple to execute, is but moderately painful and for such a short time as to be not objectionable to the patient.

Kaufmann in 1932 at the Charité in Berlin using the same preparations as in these experiments obtained what he considered full progesterational response from the endometrium. Werner and Collins working with castrated women, as well as Kaufmann working with intact women with amenorrhea obtained proliferating endometrium and subsequent bleeding with only folliculin. The purpose of the trials reported here was to repeat Kaufmann's work as well as to test if possible the value of the suction technique in studies of the endometrium. If the specific effects of each hormone on the endometrium can be thus determined, such a method offers a simple objective test of the normality of the follicular apparatus. The former common clinical assumption that the ovary is functioning properly and ovulation occurring, if menstruation takes place regularly, is of course no longer justified. Bleeding from the interval type of endometrium, produced if only folliculin is exhibited, has been repeatedly brought about in human beings (Kaufmann, Werner and Collins). As has been said, it occurs normally during the non-mating season in monkeys (Hartman, Corner) when follicular development is but partial, ovulation does not take place, and no corpus luteum is formed. On the other hand failure to menstruate in a mature human female can no longer be always attributed to persistent corpus luteum, a fallacy based on the probability that the true corpus luteum of pregnancy prevents menstruation in the first few weeks, and that in the nonpregnant the ripe, false corpus luteum inhibits the bleeding which will occur when the luteal body regresses. In some of the amenorrheics at least, as is the case in the four described here, not only is there no probable corpus luteum effect demonstrable in the endometrium before treatment but not even any extensive folliculin effect.

*The materials used in the study were generously supplied by Schering Corporation of New York.

†A suction curette as described may be obtained from Hillier & Heuser, Cambria Street, Boston.

REMARKS

In considering the preceding experiments it must not be forgotten that all these women were intact mature females of childbearing age, and although amenorrheic for many months before the observations recorded here were made, none of them gave such evidence of ovarian atrophy as we see in normal women long past the

menopause In such women as these, a sporadic autogenous menstruation is not at all impossible or even unlikely It merely seems as if this were not the case with these particular women, and that therefore the endometrial changes described can probably be considered due to the preceding medication

Likewise we must remember that all parts of the uterine lining do not at any one time conform to a given cytological set-up This difference in response to endocrine stimulation on the part of various sections of the endometrium may be teleological,—witness the localization of decidua in the monkey (Wislocki) Perhaps something similar occurs in human beings, and will explain the occurrence of placenta previa as due to a lowering of the threshold for decidual change in a portion of the uterus not usually susceptible, or a resistance where it normally occurs It may at all events be said that in these as well as other studies of the endometrium to be reported later, there has been not only a great similarity in all the fragments of mucosa obtained at any one time, but these have agreed in cytological picture with what we would expect from experience with laboratory animals and surgical specimens from human beings Regarding deciduomata, it may be said that in further studies not reported here, the greatest variation among the fragments was in the degree of predecidual response on the part of the stroma cells Because of the uniformity of the fragments and because of their agreement with theoretical expectancy it seems as if the Klinger-Burch suction curette is a very serviceable instrument, and that the specimens obtained give a correct picture of endometrial response

If this is so, and these women can be assumed to have had quiescent ovaries during the trials, it has been demonstrated again that in human females proliferation of the endometrium is caused by folliculin If furthermore, we are willing to identify human with monkey physiology it has been reciprocally shown that Proluton-B is an active preparation of corporin, and that the secretory activity of the glandular epithelium is a specific corporin effect Kaufmann's experiments would be thus corroborated

The possibility of anovulatory flow has also again been demonstrated We know that this occurs in human beings with granulosa cell tumors To occur in otherwise normal human beings, sterility patients, for instance, we need only assume a sufficient folliculin production in follicles which do not thereby rupture with ovulation I believe the frequency of this has been overestimated, a creed which we are now using the suction curette to test

In the experiments reported, the time at which the flow occurred after the injections were stopped, is interesting In none did stain-

ing appear during the treatment In L— and R— the flow appeared six days after the last injection of Progynon-B during the first five of which corporin was given M— in one experiment, the second with her, waited ten days after the last injection of Progynon-B before flowing but during the first nine of these ten days Proluton-B was being given She, too, then, flowed the day after Proluton-B was stopped In the first trial with M—, she waited four days after the last Proluton-B injection, but she was getting Progynon-B with each Proluton B It seems therefore as if perhaps folliculin has a latent protective period for four days when given in these doses, but that Proluton-B protects the endometrium from flow only while it is given As exceptions, C—, in the second experiment, with Progynon-B waited only two days before flowing after the last injection whereas M—, in the third trial with her when only theelol was used, did not flow until nine days after the last injection

From the study of the endometria reported here and from many others it is clear that in neither folliculin nor in corporin have we the whole secret of bleeding It seems true, however, that massive extravasation of blood into the stroma takes place when folliculin is acting on the endometrium, but that the mucosa holds it in bounds while either folliculin or corporin is active

What is the clinical value of such findings as these? It will be noted that to secure most of the periods of flow from secretory endometrium, 50,000 ru of folliculin and 50 rabbit units of corporin were used during the three weeks preceding the flow Attempts demonstrably to influence the endometrium with smaller doses were unsatisfactory The present cost of effective therapeutics, then, at least five hundred dollars a month, is prohibitive, when one considers that the only human benefit from the flow is psychic But are we sure that only the endometrium is objective in this reaction to the ovarian hormone? There is much theorizing and a little experimental evidence that the ovary, too possibly secondarily to anterior pituitary changes, is responsive to its own secretions If this be so, and we can learn the mechanism may we not eventually strike nearer the source as well as the disadvantage of amenorrhea, by stirring up the ovary through its own hormone?

SUMMARY

The cyclic changes in the endometrium of mature human beings have been described and correlated with synchronous changes in the ovaries

A modification of the Klinger-Burch suction curette has been described and shown to be of service in the study of the endometrium and

through this of female sex-endocrine physiology

Seven instances of artificial menstruation in four patients have been described. In three instances the flow followed injections of only folliculin, in the other four folliculin was followed by corporin. When only folliculin was used the flow is shown to have been from endometrium in the proliferating phase. When both were used a true secretory endometrium was generated.

The changes in the endometrium were accomplished only with relatively huge doses of hormones.

NOTE

The writer is gratefully indebted to Dr. Frank A. Pemberton and Dr. George Van S. Smith for essential assistance in the work reported.

He wishes also to thank the Schering Corporation for the supplies of Progynon B and Proluton B, and Parke Davis and Company for supplies of theelol.

Because the colorless prints of the stained sections of endometria represent them so poorly, the writer will be glad to lend the sections to those who wish to study them.

CONGENITAL SCLIOSIS*

A Review of Seventy-Seven Patients

BY JOHN G KUHN'S, M.D.†

CONGENITAL scoliosis is the name usually given to lateral curvature of the spine which is present at birth and which is due to abnormalities in the vertebrae or their contiguous structures. There has been a tendency in recent years to group as congenital scoliosis only those cases which have shown vertebral deformation in roentgenograms¹ interpreted as congenital in origin. But reports have appeared in the literature² and observation has also been made in this clinic of definite scoliosis present at birth without any changes in the spine demonstrable in roentgenograms. This latter type of scoliosis is not common. It usually corrects readily under treatment and subsequently remains normal. In the series of cases reviewed here such congenital scoliosis without demonstrable abnormalities in the spine has been purposely omitted.

This study was made of all the children with congenital scoliosis who were seen in the Scoliosis Clinic of the Boston Children's Hospital from the organization of the Scoliosis Clinic in 1908 until the present time. There were sev-

enty-seven children with this type of deformity among 1483 cases of scoliosis treated in the clinic, of these 681 were diagnosed as structural scoliosis and 802 as physiological or functional scoliosis. This would give a frequency for congenital scoliosis of eleven plus per cent in the total number of cases of structural scoliosis. There were fifty-six girls and twenty-one boys. In these seventy-seven children data were collected in regard to the family and prenatal histories, the presence of other congenital defects, the type of curve, the nature of the spinal abnormalities, the kind and duration of treatment and the present condition, particularly in regard to the function of the spine.

Congenital scoliosis was thought to be extremely rare before the present century. First described by Mary³ in 1700, Coville⁴, in 1896, found it only once in an examination of one thousand children and was able to collect only a few cases from the literature. With the advent of the roentgenogram this deformity was discovered more easily, so that now it is not considered uncommon. There are no figures available in regard to its relative frequency in comparison with other deformities appearing at birth. Statistical studies of lateral curvature

*From the Scoliosis Clinic Boston Children's Hospital.

†Kuhn's John G.—Assistant Orthopedic Surgeon Children's and Robert B. Brigham Hospitals. For record and address of author see "This Week's Issue" page 1344.

show that the incidence of congenital scoliosis in structural scoliosis varies between three per cent⁵ and eleven per cent⁶

Small groups of children suffering from congenital scoliosis have been studied by a number of observers. The vertebral abnormalities seen in roentgenograms were described by Putti⁷ who made a careful review of the theories of their pathogenesis. Sever⁸ studied a number of children with congenital defects of the spine and ribs from the standpoint of their etiology. Wierzejewski⁹ divided congenital defects of the vertebrae into five groups: 1, numerical variations; 2, disturbances in segmentation; 3, separation of the vertebra into parts; 4, wedge-shaped vertebrae; 5, irregularities in the development of the spinal joints. Hodgson¹⁰ in a discussion upon the grouping of these deformities showed the difficulty that one meets in finding a classification adequate for all of these abnormalities.

There are many theories upon the etiology of this condition.¹¹ Many of them are now only of historical interest. From the studies of Bardeen¹² and others¹³, it has been shown that these abnormalities arise before ossification occurs in the spinal column that is during the first six weeks of fetal life. The precursors of the vertebrae which develop from the sclerotomes are to a large extent potentially equal; their subsequent development (that is their segmental differentiation) depends largely upon their regional environment. A temporary disturbance in the development of adjacent muscles or viscera could cause a vertebra in a spinal segment to be different from the others as is occasionally observed at the dorsolumbar and lumbosacral region. Putti⁷ believed that a study of the phylogenetic relationship to lower vertebrates would help in the explanation of many vertebral deformities. Coville⁴ and Mouchet¹¹ have suggested a disturbance in the nutrition of the vertebral body at the time of chondrification as a cause of some of these abnormalities. Stockaid¹⁴ and others have shown that thermal and chemical changes can modify greatly the development of the embryo. Many factors may play a part in arresting, retarding, or accelerating the development of a special part such as a vertebra. Reid¹⁵ has suggested disease in the mother during early pregnancy as a possible cause. How much we can modify these suggested causes in preventing vertebral deformities must remain conjectural in the present state of our knowledge.

There is little evidence to support the theory that these abnormalities are hereditary except in rare instances of multiple physical deformities found where tendencies to such malformation are present in both parent cells.¹⁶ In this group of cases a history of physical deformities

in the immediate family was obtained in only two cases, one a unilateral club-foot in a brother, the other deaf mutism in a sister. The prenatal histories revealed nothing unusual in any of the cases where they could be obtained. Two of the children in this group were born prematurely: one at the eighth month and one at eight and one-half months of the pregnancy.

The types of curves found, showed no definite predilection to any particular form of curvature. Table 1 gives the frequency of the different kinds of curvature. Most of the curves were double curves, those with convexity to the right in the dorsal region and to the left in the lumbar region were the most common. There was one triple curve. In practically all instances the curve whether single or double in form remained the same in form although not in severity throughout the period of observation. This characteristic of relative fixation of the curvature in congenital scoliosis has been mentioned by a number of observers.¹⁷

Congenital scoliosis is frequently not noticed as are other forms of scoliosis until severe deformity occurs. In these children the curvatures were noticed at birth in only eighteen during the first six months in eleven before two years in nineteen and after six years in fourteen. No subjective symptoms were present in any of the cases. Other signs besides the curvature, which led the parents to seek treatment, were a high shoulder due to an associated Sprengel's deformity in one child. A short neck due to congenital abnormalities of the cervical spine¹⁸ led to the diagnosis in two children. Hypertrichosis over the spinal column caused the parents to seek medical advice in three instances. Asymmetry of the body exclusive of the spine, was found by two of the mothers.

It is almost impossible to group cases of congenital scoliosis according to the type and extent of the spinal deformity. While certain kinds of deformities of the vertebrae and ribs appear again and again, the pattern is never duplicated, and there are no two spines with like deformities in this entire group. Table 2 gives the frequency of the usual deformities in

this group of cases. The numerals refer to the number of cases in which the listed deformity was observed.

Spina bifida occulta	21
Platyspondylisis	4

FIG 1 Roentgenogram of child of five mentioned in text. There are twelve ribs on the right side and eleven on the left side. There is fusion of the ribs from the third to eighth ribs on the left side. There is a spina bifida occulta of the entire dorsal and lumbar spine. There are deformities of all of the dorsal vertebrae.

FIG 2 Roentgenogram of child of four showing deformities confined to the cervicodorsal junction. The fourth and fifth cervical are fused on the left side. The sixth cervical shows a hemivertebra on the right side. The seventh cervical is bifid.

In only three instances was a single deformity found. In all of the others multiple spinal deformities were present. In one case a child, who is now five, almost all of them were present (fig 1). This child has a severe right dorsal-left lumbar curvature with marked asymmetry of the thorax, but is very active nevertheless and has no subjective symptoms. More deformities, particularly in the laminae and articular facets will probably become evident as ossification progresses in the vertebrae of the younger children. Bifid vertebrae and hemivertebrae were the most common deformities found.¹⁹ Böhm²⁰ had considered such abnormalities as the cause in certain cases of developmental scoliosis in his study in 1906. The findings in the roentgenograms agreed with the observation of Mouchet and Roederer²¹ that hemivertebrae were prac-

tically always associated with more important deformities elsewhere in the spine. In this series no spine showed a single hemivertebra as the only abnormality.

Congenital defects were more commonly observed at the cervicodorsal and dorsolumbar regions of the spine, points where anatomical structures as well as function in the vertebrae are differentiated (fig 2). Costal anomalies were associated in every instance with extensive vertebral defects. Segmental variations, i.e., a difference in the number of cervical, dorsal, and lumbar vertebrae, were observed in only four cases. Wedge-shaped vertebrae were seen in the roentgenograms from four spines. In two where earlier studies had not been possible it could not be determined whether the wedge-shaped vertebrae were congenital or developmental deformities. Platyspondylism²⁰, an unusual flattening of the vertebrae, was seen four times. All of these defects remained practically unchanged in subsequent roentgenograms throughout the growing period.

Associated abnormalities in other parts of the body are found not uncommonly with congenital scoliosis. In one child there was an absence of all of the fingers. One child had syndactylism. Clinodactylism²³, a flexion deformity of the fingers due to contracture in the subcutaneous tissues on the palmar side of the fingers, was observed in one case. A Sprengel's deformity was present in three. In two children cervical ribs were found. A unilateral absence of the pectoralis major muscle was observed in one boy. One child showed congenital deafness in both ears. This series of associated deformities, while too small to give much weight to any argument, makes one wonder if in these instances one was dealing with a weakened but visible germ plasm. Later studies of the offspring of these individuals will be of interest.

Many different opinions in regard to the prognosis of congenital scoliosis have been given in the past. This has resulted probably from the great variation in the kind and extent of spinal deformity. Congenital scoliosis follows the same mechanical laws in its progression or its improvement as any other type of scoliosis. The greater rigidity of the spine which is usually found in congenital scoliosis tends to make its progression somewhat slower and its correction somewhat more difficult. Extensive costal and vertebral anomalies which are always associated with muscular defects frequently lead to extensive asymmetry of the thorax, much worse than one would expect from the extent of the scoliosis, as Sternberg²⁴ has shown. In spite of these, however, function is carried out, by what structures are present, surprisingly well.

Some of the less serious cases with vertebral anomalies which do not alter seriously the alignment of the spinal column seem to remain practically unchanged whether treatment is given or not. Each case is an individual problem and no natural course can be plotted for any single case or group of cases as the study of the end results in this series shows.

We believe that a fair prognosis is justifiable in congenital scoliosis, if the full cooperation of the child and the parents can be secured. Our own experience confirms the statement, frequently made, that increasing deformity is readily prevented, and that in infancy the scoliosis is often almost completely corrected without great difficulty. Unfortunately, many of the cases studied here have not shown so happy an outcome. Treatment was often irregular, soon discontinued, or improperly followed. In recent years due to the economic depression, many children have changed their residences without leaving a trace whereby our social service workers could follow them. Irregular practitioners, and appliances advertised with extravagant claims, have misled not a few.

Our observations lead us to conclude that congenital scoliosis is never wholly cured except in the occasional case, with mild deformity, that is followed carefully from earliest infancy until growth is obtained. The greatest improvement in bodily symmetry and the correction of the scoliosis has been seen in those children who have been followed carefully since birth. We are accustomed to measure improvement by two methods, first, by the general appearance and functional ability of the body, often the most convincing to parents, and secondly, by such clinical measurements as we can make of the spine and thorax including photographs and x-ray examination. As table 3 shows, a large number of these children demonstrated practically no change in their scoliosis. In two of these no treatment of any sort had been given, they were simply kept under observation for a number of years. Both of these were mild curves with only slight vertebral abnormality. Failure to show improvement in twelve resulted from the severity of the spinal deformity, from bad judgment in the type of treatment given, or from poor cooperation on the part of the patient. Two of these children have died, one, a girl of twenty, with scoliosis unchanged, from pneumonia, and the other, a girl of seventeen, whose scoliosis had grown worse, from heart disease. Thirteen children could not be traced.

TABLE 3
END RESULTS

Cured	0 (known)
Improved	24
Condition unchanged	26
Worse	12
Condition unknown	13
Dead	2

Treatment in this group of children varied greatly in this twenty-five year period as is shown in table 4. While noteworthy advances in the treatment of scoliosis have come in the last decade, efficient treatment for all cases of congenital scoliosis is still unknown²⁵. The earlier treatment is begun and the more uninterrupted.

ly it is continued to the end of the growing period the better the outcome will be

Eight children were given no treatment. Three of them came simply for consultation, two were kept under observation and in the other three, treatment was refused. Exercises alone have been rarely used except in the very mild forms of congenital scoliosis. The large number given in table 4 includes many where a preliminary series of exercises was given preparatory to the use of apparatus but where, as is found in all outpatient clinics, treatment was discontinued before the second step in the treatment was reached. Following the observations of Bradford and Lovett in this field, exercises were given in addition to support in almost all of the cases. Plain jackets were used for simply holding the spines when no further correction could be obtained, and support of the spine was necessary. They were used instead of more elaborate braces, usually for the sake of economy. "Derotation jackets" were found effective only in the exceptional case. Because of the fixed anatomical abnormalities, pressure upon the ribs rarely produced much change in the deformity. The author, who has used both "derotation jackets" (with pressure upon the prominent ribs) and "lateralization jackets" (with hinge and lateral turnbuckle), has observed much more effective correction from the latter method in congenital scoliosis. Posterior plaster shells for the recumbent treatment of infants were used in thirteen cases. In all of these children the shell was followed by some form of ambulatory support if the children remained under treatment.

ent 4 Such upbuilding measures as are indicated to improve the general health. Any treatment that is undertaken should continue until full growth in stature has occurred, since the changes which come with increase in height modify the mechanics of the spine to a certain degree throughout the growing period.

For congenital scoliosis in infancy we have found the most effective treatment to be the use of a molded plaster shell which holds the spine in a slightly overcorrected position. This can be made while the child is held with the curvature overcorrected as described by Harrenstein² or a turnbuckle shell can be given, as reported by Brewster²⁶. Such procedures have been found to be far more effective than the strapping of the child to a Bradford frame. Where there are severe congenital abnormalities it has been found advisable at times to continue treatment in recumbency with a plaster shell, long beyond the usual period for beginning to walk. In the less severe cases at the usual time for walking, a plain plaster jacket is applied with the child in suspension, and the child is permitted to creep and walk in this. Where much curvature persists, a turnbuckle jacket is used²⁷. Reinforced corsets of canvas or leather have been found unsatisfactory in maintaining the correction in the spine except in the congenital scoliosis of mild degree.

In the last ten years exercises have been given in practically all cases of congenital scoliosis in conjunction with some type of support. These exercises have been of two kinds, mobilizing exercises to overcome contractures of the muscles and ligaments, as described by Lovett²⁸, in order

TABLE 4
TREATMENT

Treatment	Cases	Present Condition			
		Improved	Unchanged	Worse	Unknown
No treatment	8	0	4	0	4
Exercises alone	21	5	9	2	5
Turnbuckle jacket	18	10 (1 dead)	5	3	0
Plain plaster jacket	6	2	2	1	1

Plaster shell	5	0	1	3	1
Derotation jacket	3	1	1	1	0
Bradford frame	2	0	1 (dead)	1	0
Corset	2	1	1	0	0
Operations					
Fusion of spine	2	1	1	0	0
Lowering of scapula	2	1	0	1	0

Good results can be obtained by many methods, as the end-results from this clinic have shown. Adequate treatment for congenital scoliosis must include 1. Mobilization of the rigidity and lessening of the curvature of the spine, which should be carried out not too rapidly or forcefully. 2. Strengthening of the muscle groups which support the spine, by exercise. 3. The development of the best posture obtainable with the deformities which are pres-

that the curvature might be lessened, and postural exercises to secure better general muscular development, to obtain better respiratory function and to improve the balance of the spinal column. In a number of the cases where partial correction of the curvature had occurred, the children were able to maintain the improved position with their own musculature. Attempts at correction both by turnbuckle jackets and exercises were continued as long as im-

provement in the spinal deformity was observed. Jackets and other spinal supports were removed gradually when no further correction could be obtained, and when the muscles which support the spine were well developed and the poise of the body was good.

Vigorous redressment as advocated by earlier writers has not been used. The rigidity and the bony deformities make it both a difficult and dangerous procedure in congenital scoliosis. Correction even by slow stretching is a sufficiently difficult procedure except in the very young. We have found that it is much easier to start in infancy and guide the spine into straighter growth with the gradual increase in height than it is to correct deformities. Some improvement in the spinal and thoracic deformities can be obtained even in adults, but good functional as well as anatomic rehabilitation, at least in the severe cases, can only be expected where the spine is made to grow relatively straight and is used from early childhood in as nearly normal function as possible.

Removal of a portion of a vertebra²⁹, or of a hemivertebra has been reported³⁰. In none of the cases reported where this operation has been performed has sufficient time elapsed so that full appraisal of this therapy can be made. In practically all cases a hemivertebra or a wedge-shaped vertebra is found with other deformities in the spine. The successful removal of such vertebrae will only partially correct the disturbance of balance. While this procedure was considered in one case, it has not been performed in this clinic. An attempt has been made to prevent increase in deformity by early spinal fusion³¹ in only one case. In this case while increase in the curvature has been helped materially by spinal fusion, support and supervision will be necessary for a number of years more. Fifty-two of the children in this series are still under treatment either in this clinic or under the care of other physicians.

Conclusions 1 Congenital scoliosis is not an uncommon spinal deformity. It comprises 11 per cent of the cases of structural scoliosis seen at the Boston Children's Hospital. 2 The vertebral deformities occur in early fetal life. We do not know as yet how to prevent their occurrence. 3 Early diagnosis is made too rarely. The deformity is usually the only physical sign

4 Multiple deformities scattered throughout the spine were found in all except three children. 5 Treatment must begin early if good functional and anatomic correction is to be obtained. 6 Supervision must be continued until full growth has occurred.

THE ANEMIAS OF PREGNANCY*

BY MAX DAVIS, M.D.,† AND ELISABETH W. WALKER, A.M.†

THE problem of anemia during pregnancy has not received so much attention from the medical profession as it deserves. Very few

clinics, and even fewer private practitioners, go to the trouble of performing routine blood counts and hemoglobin determinations on their pregnant patients, despite the fact that a patient with anemia is definitely less fit for the intense strain of labor. The attention of the obstetrician has been focused with great keenness, and justly so, upon the dangers of toxemia, but his interest should also be sufficiently aroused

*From the Robinson Memorial, the Obstetrical Department of the Massachusetts Memorial Hospitals and from the Boston University School of Medicine. Delivered before the New England Obstetrical and Gynecological Society on November 30 1932.

†Davis Max—Instructor in Obstetrics and Gynecology Boston University School of Medicine. Walker Elisabeth W.—For records and addresses of authors see This Week's Issue page 1344.

to consider the anemia of pregnancy, which is an ever-present, though less threatening problem than the toxemias, and occurs in a far larger proportion of patients than do the latter

Two distinct types of anemia occur during pregnancy—one, a typical secondary anemia, the other, resembling pernicious anemia in its blood findings. Until very recently, most of the studies dealing with the anemias of pregnancy focused their attention upon the latter group, which occurs but rarely. This type is usually amenable to treatment only by blood transfusion. It will not be further considered in this discussion, as in our series we did not meet with a single typical case of this group.

The exact etiology of the secondary anemia has not been definitely established. Various causes have been assigned as possible etiologic factors, but no one of them has as yet gained a clear title to this distinction. For example, overdestruction of the red blood cells in the placenta by various hemolysins with abstraction of the iron by the fetus, deficiency of replacement of these destroyed cells by the blood-forming organs, hydremia, foci of infection, a preceding anemia, vitamin deficiency—all have been accused as etiologic agents. Some proof has been advanced for all of these factors, and it is possible that a combination of several of them may be the final solution.

During the last three or four years, the work of Galloway, Moore, Bland, Weiss, Strauss, and others has helped to bring this problem somewhat to the fore. These investigators have found that forty-seven to sixty-five per cent of pregnant women tend to develop anemia during pregnancy, and that this anemia is progressive. It has also been established that a certain number of these patients recover spontaneously after delivery. It is felt that although a definite etiologic factor is not yet known, nevertheless empirical treatment for the anemia should be undertaken the better to prepare the patient for the hazards of labor and the puerperium. Various substances have been suggested for treatment, with diverse reports as to their value.

Our own study was undertaken in the effort to establish in a series of untreated cases the exact degree of the progress of the anemia during pregnancy. This was accomplished by doing frequent complete blood counts—red cell, white cell, and hemoglobin determinations, and differential counts—on each patient throughout her pregnancy and puerperium. It was also decided to test the value of various preparations in treating another series of patients, and to check the blood findings in exactly the same manner. The patients were all followed in the prenatal clinic of the Robinson Memorial, the blood for examination being taken by three dif-

ferent technicians.* The counts were all performed by one of us, Mrs. Walker, in order to establish uniformity in the results. Two hundred cells were counted for each differential count. The hemoglobin determinations were all performed by the Hayden-Hauser hemoglobinometer. From six to ten counts were taken on most of the patients, counts being done at each visit to the prenatal clinic, and also within twenty-four hours of delivery, and at periods of one week, two weeks, and six weeks postpartum. Sixty-nine patients were in the untreated group, and one hundred and twenty in the treated group. The latter were subdivided into six sub-groups of twenty each, each group receiving a different preparation†. Unfortunately, as will be seen from the tables below, thirty-one of the treated patients could not be followed throughout, because they either left the clinic or refused to continue with the medication.

We classed as anemic all patients whose blood findings fell below the criteria accepted as the lowest limits of the normal, namely, a hemoglobin of seventy per cent and a red cell count of three and one-half million. Thus, we discovered that forty-three per cent of the 161 patients tested had a secondary anemia. If, however, we also included a borderline group which had a hemoglobin percentage between seventy and seventy-seven, red cell counts between three and one-half and four million, and the signs of secondary anemia in the smear, our percentage of such patients rose to fifty-six per cent. It is particularly interesting to note that the percentage of anemic patients changed very markedly with the seasonal variation of the year. Of the 161 cases, examined in the late summer and early fall, 43 per cent showed an anemia. These formed the untreated control group. Our treated cases, selected in February and March, were chosen from a group of 133 patients of whom ninety per cent had anemia‡.

Table I below shows the average counts in the untreated anemic cases throughout the period in which they were followed.

It is thus seen that in untreated cases, the anemia is progressive, and that there is a moderate spontaneous recovery during the lying-in period. We did not find any diminution in the anemia in the two-week period preceding term, as has been suggested by some authors. We did, however, find a definite increase in the anemia at the examination at the sixth week postpartum.

*We wish to express our thanks to Dr. F. L. Belding for his cooperation in permitting the Misses Hinckley and Bland and Mrs. Stewart from his laboratory to take these counts for us. We also wish to thank the latter for their aid and interest in this work.

†We wish to thank the various companies that so graciously furnished us with all the necessary material for carrying out this study. The Myeladol was furnished by the Upjohn Company, the Neoboviline 23 by the Bovinine Company, the iron manganese and copper tablet by the G. D. Searle Company, the liver and iron by Eli Lilly Company and the ventriculin and iron by Parke Davis & Co.

‡If the borderline cases are also included the percentage of anemia rises to ninety-five per cent.

The disadvantages incurred by lack of treatment were no doubt aggravated by the inability of the patients to afford proper food and help at home on returning from the hospital. The resultant extra work demanded from the weakened patient, thus definitely retarded her recovery

in respect to the maintenance and increase of the hemoglobin and red blood cells in comparison with the condition of the patients before treatment began was ventriculin and iron, and the second in rank was liver and iron.

Table VIII illustrates a comparison of certain

TABLE I
AVERAGES OF BLOOD FINDINGS IN THE UNTREATED ANEMIA CASES*

	Hgb	Rbc	C I	Wbc	PMN	Lym	End	Eos	Bas
Second Trimester	64.9	353.3	0.93	9,590	74.9	19.9	4.1	0.77	0.23
Third Trimester	62.8	345.5	0.96	9,992	72.5	20.8	6.11	0.72	0.18
First 24 hours postpartum	64.3	368.5	0.86	13,729	77.4	16.7	5.3	0.57	0.16

Ventriculin and Iron	66.6	378.1	0.89	10,000	73	18.4	7.9	0.70	0.04	18

*The dosage of these substances was as follows:

Myeladot—one tablespoonful t. i. d.
Neobovinine-20—one tablespoonful t. i. d.
Iron, Copper, Manganese, Calcium—2 tablets t. i. d.
Blauds with Arsenic and Strychnine—2 tablets t. i. d.
Liver and Iron—one teaspoonful t. i. d.
Ventriculin and Iron—10 to 20 grams daily.

†Each fluid ounce contains:

Super D cod liver oil (Upjohn) 120 minims
Glycerinated Extract Red Bone Marrow 10
Iron and Ammonium Citrate 4 grains
Malt extract qs

‡An original organic compound of liver extract and beef hemoglobin. Each tablespoonful contains the equivalent of 0.53 ounces of fresh whole liver.

The tables show that treatment definitely stops the downward curve during the second and third trimesters, particularly by raising the hemoglobin percentage. The recovery after delivery is more rapid, also, being somewhat more evident in the percentage of hemoglobin than in the red cell count, although the latter also is raised. It must not be forgotten that this improvement is evident despite the fact that the economic circumstances of these patients do not permit them the best possible care for their condition. The white blood cell count and the percentage of polymorphonuclear cells rise definitely during labor and remain high for the first few days after delivery, gradually returning to normal by the second week postpartum. As for the relative value of the various preparations used in this study, the tables again indicate clearly the results. The best preparation

and there were almost five times as many premature deliveries. These two factors probably account for the increased fetal mortality in the untreated cases. Labor was definitely longer in the untreated cases. Probably the most important difference between the two groups was the higher percentage of morbidity†, — in the untreated group, 27.9 per cent as against 11.2 per cent in the treated group. These are the infections which are so dangerous to the future health of the mother, and anything which will help to prevent them is certainly of great value in the care of the patient. We do not mean to imply by table VIII that anemia is the cause for the differences indicated therein. It

	Untreated (69 Cases)	Treated (89 Cases)

is known that a patient with lowered resistance is more liable to unfavorable complications during pregnancy, labor, and the puerperium. Therefore, it is fair to assume that any condi-

cluded under the head of such aggravating factors

TABLE VIII

COMPARISON OF VARIOUS FACTORS IN THE TREATED
AND THE UNTREATED CASES

	Untreated (69 Cases)	Treated (89 Cases)
Cases with systolic pressure above 140	4.9%	2.2%
Cases with systolic pressure below 100	48.9%	42.6%
Premature deliveries	4.9%	1.1%
Average length of labor		
Primiparae	22.8 hrs	15.6 hrs
Multiparae	13.4 hrs	11.1 hrs
Morbidity during puerperium	27.9%	11.2%
Maternal mortality	1.9%	0
Fetal mortality		
Premature	2.5%	1.1%
Full term (alive)	1.9%	1.1%
Stillborn (full term)	2.5%	1.1%
Average weight of babies	7.4 lbs	7.6 lbs

tion which tends to lower the patient's resistance may be considered an aggravating factor of such complications. And since anemia definitely lowers the patient's resistance, it must be in-

SUMMARY

- 1) Approximately 64 per cent of pregnant women develop anemia. This high average is the result of including the high percentage of anemic patients found in the late winter months. If this latter group be omitted from the average the per cent of patients with anemia falls to 43.
- 2) This anemia is progressive and is followed by a moderate spontaneous recovery after delivery.
- 3) Treatment improved the anemic condition, and made possible a more speedy recovery after delivery.
- 4) Routine examination of all pregnant patients for anemia is thus definitely indicated and appropriate treatment should be administered.
- 5) The relative success with various products in the treatment of these cases is shown.
- 6) There were more premature deliveries, a greater number of toxemias, a higher fetal mortality, a higher morbidity, and a longer labor in the untreated cases. We are not yet prepared to say positively what influence anemia and its treatment have upon these conditions.

BRONCHOSCOPY IN THE TREATMENT OF
PULMONARY ABSCESS AND BRONCHIECTASIS*

BY LOUIS H. CLERF, M.D.

BEFORE proceeding with bronchoscopy in the treatment of pulmonary abscess and bronchiectasis, one must bear in mind that its value is not entirely dependent on mechanical aspiration of pus. While drainage, considered in its broadest sense, is the most important part in treatment, a knowledge of etiological factors and other data is imperative to intelligently outline a plan of treatment. Bronchoscopy is helpful and in certain instances it is indispensable in securing this information.

Practically all the patients sent to the Bronchoscopic Clinic for treatment had been previously under medical observation for variable periods of time. Roentgen examination, repeated sputum studies and other necessary diagnostic procedures had been carried out. One

would therefore assume that a diagnosis of pulmonary abscess or bronchiectasis could be accepted and bronchoscopic aspiration instituted to supplement the general medical treatment. Experience, however, has shown that a diagnostic bronchoscopy is often indicated before arriving at final conclusions. A certain number of cases of pulmonary abscess involving a lower lobe, suggesting that they were nontuberculous in origin, have been diagnosed as tuberculosis on the basis of finding tubercle bacilli in the bronchoscopically removed secretion although repeated sputum studies had previously been negative. For that reason it is important to secure certain data before proceeding with a preconceived plan of treatment.

Pulmonary abscess—In our experience at the Bronchoscopic Clinic a history of surgical operation about the throat or mouth commonly performed under general anesthesia was elicited in over 60 per cent of the cases of pulmonary ab-

*Read before the Eastern Section of the American Sanatorium Association, Glenloch, N. J.

†Clerf, Louis H.—Professor of Bronchoscopy and Esophagus copy Jefferson Medical College, Philadelphia. For record and address of author see "This Week's Issue" page 1344.

secess In addition, a majority of the abscesses were monolobar and more than 50 per cent involved an upper lobe. This should suggest the possibility of aspiration as an etiological factor and should also indicate the need of ruling out a bronchial foreign body. Curiously, demonstrable foreign bodies in the bronchus are not commonly complicated by the development of abscess. The distinction *demonstrable* is used to distinguish these foreign bodies from microscopic particles of material which I believe can very readily be aspirated and ultimately set up a localized pneumonitis, often the forerunner of abscess or of bronchiectasis. This belief is further substantiated by the excellent results often secured by prompt bronchoscopic aspiration in pulmonary complications developing within a week or ten days after tonsillectomy, tooth extraction or other surgical procedure about the mouth or throat.

Bronchial neoplasms are occasionally complicated by pulmonary abscess particularly during the latter stages of the disease. It often is a terminal complication. In a certain number, however, the symptoms and clinical findings are typical of pulmonary abscess. Practically every thoracic surgeon has had the experience of operating on a case of pulmonary abscess which later was found to be secondary to cancer of the bronchus. Primary cancer of the bronchus commonly involves the larger bronchi and is therefore accessible to bronchoscopic inspection and biopsy. Although less frequent in occurrence, benign neoplasms, broncholiths and other forms of bronchial obstruction must be considered and should be ruled out by bronchoscopy. It would therefore seem advisable when planning the treatment of pulmonary abscess to secure all possible data concerning the etiology as well as the condition of the involved lung. This can best be obtained by close cooperation of the internist and roentgenologist with the bronchoscopist and surgeon.

In the treatment of pulmonary abscess communicating with a bronchus, success is dependent on adequate drainage. Among the important factors influencing drainage are location of the abscess, presence of mechanical obstructions, as granulation tissue or inflamed mucosa, and efficiency of cilia and cough. Posture, general medical measures and the exclusion of sedative mixtures will aid in improving drainage. Endobronchial obstructions must be removed mechanically. The decision to carry out a conservative plan of treatment without or with bronchoscopy or to resort to external surgical drainage should be arrived at by consultation. The patient who presents no clinical or roentgen evidences of retention of pus requires but conservative medical care. If there is fever with clinical and roentgen evidences of inadequate drainage, measures designed to improve this are indicated. Mechanical obstruction to

drainage may result from granulation tissue, inflamed mucosa and inspissated pus, or ciliary activity and cough may be impaired by the physical characters or the quantity of pus. These conditions can be remedied bronchoscopically.

How long should bronchoscopy be continued? In a procedure of this character there can be no rule applied as to the number of aspirations or the duration of the period of treatment. The progress of the disease as recorded by frequent roentgen examinations, the bronchoscopic findings, clinical observations and the quantity of pus expectorated, must be the determining factors. If there is no improvement in the physical signs or symptoms following several bronchoscopic treatments it does not necessarily follow that bronchoscopy should be discontinued. Often fever will persist and the physical signs remain unchanged for several weeks, the roentgen findings, however, may exhibit definite improvement. The clinical course of the disease should be the determining factor in a decision whether bronchoscopy should be continued or whether surgery should be resorted to. For that reason it is important to correlate all available data in arriving at conclusions. This can be accomplished only by close cooperation. It has been the custom at the bronchoscopic clinic to have weekly conferences between the internist, roentgenologist, bronchoscopist and surgeon for consideration of these cases.

Bronchiectasis presents innumerable difficulties both from the standpoint of diagnosis and treatment. I am convinced that the medical profession, as a whole, does not fully appreciate the serious nature of bronchiectasis. It is remarkable to note that there is little in the medical literature regarding the prognosis in these cases. It should be considered as a progressive disease in a majority of cases. It should also be noted that fatal complications and sequelae are not uncommonly observed in patients with bronchiectasis. In my experience there is no pulmonary lesion that presents the problems in diagnosis that are met with in suspected or early cases of bronchiectasis. This observation is made on the basis of reports received from a large number of competent physicians who have sent patients to the Bronchoscopic Clinic either for verification of a diagnosis or for treatment of bronchiectasis. It is, first of all, necessary to ascertain if bronchiectasis is present. If present, one should ascertain the extent of involvement, particularly if unilateral or bilateral. If unilateral, one should learn if one or more lobes are involved. It is also imperative to ascertain the presence or absence of obstruction. While much of this information can be secured by physical examination and roentgen study no thoracic surgeon would contemplate surgical treatment solely on these findings. It must be recalled that nontuberculous bronchiectasis usually involves lower lobe bronchi. It commonly

begins in the smaller bronchi, changes in the large bronchi are observed only in advanced cases. Cases of obstructive bronchiectasis are more often unilateral, bronchiectasis associated with suppuration of the nasal accessory sinuses is commonly bilateral.

The instillation of iodized oil has contributed more than any one factor in aiding the roentgenologist in the diagnosis of suspected cases of bronchiectasis. The method of instillation must be left to the discretion of the examiner. In order to be effective the oil must be delivered to that portion of the bronchial tree to be examined. The bronchoscopic method possesses obvious advantages over all others in that it permits of accurate placement of the iodized oil and also aids in securing data that can be obtained only by direct inspection of the interior of the larger bronchi. In all cases of obstructive bronchiectasis, final conclusions cannot be arrived at without diagnostic bronchoscopy.

The treatment of bronchiectasis is dependent on certain data acquired in the diagnostic studies. The best results by bronchoscopy are obtained in certain of the obstructive forms. In many of these the obstruction to the bronchus can be relieved bronchoscopically and aeration and drainage reestablished. It is a recognized fact that the structural changes in the walls of a dilated bronchus as well as in the peribronchial tissues cannot be materially altered by treatment. The dilatation is permanent and tends to increase, depending on the extent of the fibrotic changes. Measures directed toward improving drainage, preventing stagnation and building up the patient's bodily resistance are palliative and must be continued indefinitely to maintain the relief obtained. Postural drainage, bronchoscopy and certain conservative surgical procedures fall in this group. One of the

advantages of bronchoscopy is that secretions are more effectively removed, unfortunately, however, it cannot be practiced as often as postural drainage.

In the present state of our knowledge the only plan of treatment for a cure of bronchiectasis is surgical extirpation. This is practiced in unilateral cases although successes have been reported in those with bilateral involvement. The nonsurgical treatment consists of palliative measures, namely posture, bronchoscopy, bronchial irrigation, intratracheal medication, vaccine therapy, general hygienic care and removal of foci of infection in the upper air passages, e.g., diseased tonsils, and nasal sinus disease. In a certain number excellent results have been secured by these measures. This has been particularly noticeable in children. It has been frequently observed, however, that symptoms often recur following an acute upper respiratory infection with bronchial extension. It is believed that the greatest field of usefulness in the conservative treatment of bronchiectasis lies in treating the young.

The treatment of bronchiectasis, is, generally speaking, very unsatisfactory. A small group can be successfully treated by surgical means. A majority of the cases can hope for temporary benefit secured by palliative measures. Measures for the prevention of bronchiectasis should receive more attention. Prompt recognition and appropriate treatment of bronchial obstruction, so-called unresolved pneumonia, postoperative pulmonary complications, pneumonitis complicating acute infections, and nasal sinus infections associated with tracheobronchial symptoms will be productive of more benefit than all of our efforts to restore to normal function a dilated, tortuous, fibrous-walled bronchus surrounded by fibrous tissue.

A STUDY OF TEN YEARS' WORK AT THE PRENDERGAST PREVENTORIUM OF THE BOSTON TUBERCULOSIS ASSOCIATION

BY JOHN B. HAWES, 2ND, M.D.,* NATHANIEL L. K. WOOD, M.D.,* AND DONALD S. KING, M.D.*

FOR the past eleven years the Boston Tuberculosis Association has maintained a preventorium for children from the city of Boston who have been exposed to tuberculosis. As the city itself makes no provision for such children, this Association determined to meet this need, in part, at least. The cost of maintenance is a large part of our annual budget and is raised from private sources without help from city or state. As doubts have been expressed as to the wisdom of continuing this work, which in

terms of dollars and cents is a large liability, we have made the following study to ascertain from the present condition of the children who attended the Preventorium during the past decade, whether the time, strength and money spent were sufficiently justified by the results obtained and should be continued.

The Prendergast Preventorium consists of a well-equipped and homelike main building which includes dormitories for sixty boys and girls together with separate buildings, including a schoolroom, workshop, sleeping pavilions as well as a swimming pool, all located on a tract of sixteen acres of land on the outskirts of Boston. The requirements for admission are that

each child shall be between seven and twelve years of age and must show definite contact with an open case of tuberculosis and have a positive von Pirquet reaction. In a few instances an intelligence test is required. There are no restrictions as to race, creed or color. The majority of these children are referred by the city tuberculosis clinics, a few come from other health or social agencies and a very few from private physicians. In what we call our "permanent beds" we have an average population of 35-40 children, the exact number depending on our budget, and during the two summer months we take in 75-100 more. The average length of stay of the resident children was 237 days and that of the summer camp children 67 days.

During the past ten years, including 34 children at the Preventorium on May 1, 1933, we have cared for 899 boys and girls. Of these 194 have been ruled out because of their short length of stay, leaving 705 children, 671 discharged and 34 in residence who form the basis of this study. There were 315 boys and 390 girls. Of the total number, 404 had been permanent residents and 301 members of the summer camp. All these children were born in this country but their parentage was widely diversified, 320 American, 121 Irish, 98 Italian, 36 Canadian, 27 Polish, among others. Of the 404 resident children, 57 had been admitted once, 14 twice, while one child had been admitted five times. Likewise, of the summer camp children, 53 had been re-admitted once and seven returned to the camp four times. This question of the re-admission of children to the Preventorium is a difficult and yet an important one to decide. On the whole, although the argument that the greatest good to the greatest number has its merits, we feel that it is better to try to do an intensive piece of work with fewer children than a poorer and inadequate job with many. Our records show that the benefits of re-admission are very definite and real, affecting not only the child but his parents and family. In many cases so extreme was the economic situation at home, that the temporary relief from responsibility of the child was of inestimable help to the tired, sick and discouraged parents. In addition, such re-admission brought about a much closer relation between our follow-up nurse and the child's family making possible improvements in the home situation that could not have been accomplished otherwise. We feel, therefore, that poor physical condition on the part of the child and an inadequate income at home are sufficient reasons for re-admission not only once but oftener if necessary to do a complete piece of work.

The physical condition of these 705 children on admission showed wide variations but all showed by x-ray definite evidence of tuberculous

infection. Two hundred and twenty-nine were manifestly in excellent condition in every way, 292, while well-developed, showed some signs of being undernourished, 91 were below par both in development and nourishment, while 68 were distinctly poorly developed and nourished. On discharge, with the exception of a very small group who went home against advice or who were discharged for the infraction of rules, all showed definite improvement, a point well confirmed by subsequent x-rays. Likewise, our records show that 90 per cent of the children who attended the Preventorium school were promoted, including a large number who had not done well in public schools prior to their admission. It was gratifying to note how rest, good food and fresh air along with new and attractive surroundings, individual attention, kindness and patience, awakened in the child an active interest to study and to learn.

An important and indeed an essential part of preventorium work is done after the child has left the institution. This consists in seeing that each child is under adequate medical supervision and is not lost sight of after discharge. This is done through an after care worker, in our case a nurse highly trained in this field. She visits each child in the home, sees that it reports regularly to the clinic or elsewhere for examination, and, of far greater importance, she obtains the cooperation of parents and other members of the family so that the training received at the Preventorium is not dropped. One of her duties, a most difficult and yet vital one, is to see that the original source of the child's infection is either eliminated altogether or reduced to a minimum, a difficult but not an impossible task. The thoroughness and efficiency of our own after care worker in this regard are shown by the fact that during this eleven-year period, out of 705 children only 29 cannot be traced, while only one has been known to have since died of tuberculosis. Nineteen children were admitted to sanatoria after leaving our Preventorium not because of the development of active tuberculosis but in the case of some as a preventive measure, beds in our own institution not being available, or with others because they had passed our age limit. At present, all but four of these have returned to their homes and to school in good condition. Two children out of 705 have since developed pulmonary tuberculosis and have had active sanatorium treatment. The following is the story of one of these.

This girl, twelve years old, was admitted to our Preventorium in very poor condition and remained 296 days, gaining twenty two and a half pounds. After her discharge, she was admitted to a sanatorium day school near her home which she attended for three years. In

addition to this she helped take care of an aunt, an active case of tuberculosis, as well as her mother who could not be persuaded to go to a sanatorium but who insisted on remaining at home, a constant source of infection. At the end of her third year in school, this girl was likewise found to have active tuberculosis and was admitted to a sanatorium where she remained for four years. In the meantime the aunt had died and the mother was finally taken to an institution. On her discharge, the girl was again referred to us and was at once admitted to our Sheltered Workshop where she has now been working three hours a day under close medical supervision for the past year and a half. At present she is in good physical condition in every way with her disease apparently arrested.

Constant and long-continued medical supervision as exemplified in this girl's case is essential to good results. Out of the total number of children included in this study 435 were found to be under good medical supervision, in 170 this was only fair, and in thirty-one it was inadequate or lacking. This group was made up of boys and girls in late "teen" age who flatly refused to go to a clinic or to consult a physician. Each appeared to be in good condition, however.

During the past year, 362 of the 636 children who had been discharged were x-rayed. Out of these, seventy suspicious cases were found, each of whom was given a careful physical examination. Of these children fifty-nine were in good condition, nine in only fair condition, while one child proved to have scoliosis and one a congenital heart. No child was found to have active tuberculosis. This group of seventy children will be watched with the greatest care.

The school records of the children discharged from our Preventorium show that up to May 1, 1933, 106 have completed high school, 158 are in high school at present, 314 are in grammar school and eighty-two left school when old enough to work. Of the 106 who graduated from high school and the eighty-two who left school, ninety-two were at work in the following fields: clerks, sales ladies, nurses, business college, doctor's assistant, chauffeur, electricians, salesmen, factory workers, companion, stenographer, mechanic, tailors, priest, nun, counsellor, maids. Five have married.

An important point in a study of this kind is to find out what has happened to those tuberculous individuals who were the original source of the infection from which these children contracted their disease. It was found that a large number of these, 65 per cent, had died previous to the child's admission to the Preventorium, and in many cases it was this that led to the discovery of the infected child. In 267 cases the source of infection had received sanatorium care. In this group precautions to prevent fur-

ther infection were fairly well carried out in the home. We were firmly convinced that our greatest problem would be with a group of 109 men and women who had received no sanatorium care, and yet much to our surprise the children coming from such homes were found to be in just about as good condition as those in other groups who had had no such prolonged exposure. We believe that it is fair to assume that this is largely due to the work of our follow-up nurse and her ability to bring about intelligent cooperation on the part of the family. This particular group is largely made up of the foreign element who do not understand the dangers of infection. It may very well be that by taking the child from such a home, opportunity for closer cooperation between the family and the nurse was given which could not have been brought about in any other way. In such families as these, slowly but surely the nurse gains the mother's confidence long before the child is discharged from the Preventorium. Then when the child finally returns home the basis for future work is laid. Then the nurse plans the child's daily routine, takes him to the clinic when necessary, helps to get aid from the city or elsewhere if needed, and arranges with clubs and settlement houses for special recreational and educational advantages. Likewise, besides her work with the individual child and family, she enlarges its scope to develop group activities for adults in these homes, such as cooking and sewing classes, family conferences, parents' meetings where talks on child care and hygiene and other topics are discussed. All this is initiated by the after-care nurse.

The following report is a typical example of the time and thought spent on one family in this way in order to safeguard the health of one Preventorium child.

A nine-year-old boy, pale, thin and sickly, was admitted to Prendergast and remained 120 days and was then discharged in good condition. In the meantime his father had died of tuberculosis so that the mother had had to break up her home and live with her parents, resulting in a thoroughly bad home situation. A small apartment was found for mother and son, the mother was well enough to go out to work and the boy, profiting by the lessons learned at the Preventorium, washed the breakfast dishes, swept the floors and made the beds. Through our nurse he attended the nutrition class at school and so had a suitable noon meal each day and after school hours joined a recreation group at a local settlement house which he attended regularly as well as its summer camp. At the present time his physical condition is good and he is examined and x-rayed regularly. His home is cheerful and happy and the future for him is bright.

What may one conclude from this summary of the results of ten years' work with children at our Prendergast Preventorium? Very little,

each child shall be between seven and twelve years of age and must show definite contact with an open case of tuberculosis and have a positive von Pirquet reaction. In a few instances an intelligence test is required. There are no restrictions as to race, creed or color. The majority of these children are referred by the city tuberculosis clinics, a few come from other health or social agencies and a very few from private physicians. In what we call our "permanent beds" we have an average population of 35-40 children, the exact number depending on our budget, and during the two summer months we take in 75-100 more. The average length of stay of the resident children was 237 days and that of the summer camp children 67 days.

During the past ten years, including 34 children at the Preventorium on May 1, 1933, we have cared for 899 boys and girls. Of these 194 have been ruled out because of their short length of stay, leaving 705 children, 671 discharged and 34 in residence who form the basis of this study. There were 315 boys and 390 girls. Of the total number, 404 had been permanent residents and 301 members of the summer camp. All these children were born in this country but their parentage was widely diversified, 320 American, 121 Irish, 98 Italian, 36 Canadian, 27 Polish, among others. Of the 404 resident children, 57 had been admitted once, 14 twice, while one child had been admitted five times.¹ Likewise, of the summer camp children, 53 had been re-admitted once and seven returned to the camp four times. This question of the re-admission of children to the Preventorium is a difficult and yet an important one to decide. On the whole, although the argument that the greatest good to the greatest number has its merits, we feel that it is better to try to do an intensive piece of work with fewer children than a poorer and inadequate job with many. Our records show that the benefits of re-admission are very definite and real, affecting not only the child but his parents and family. In many cases so extreme was the economic situation at home, that the temporary relief from responsibility of the child was of inestimable help to the tired, sick and discouraged parents. In addition, such re-admission brought about a much closer relation between our follow-up nurse and the child's family making possible improvements in the home situation that could not have been accomplished otherwise. We feel, therefore, that poor physical condition on the part of the child and an inadequate income at home are sufficient reasons for re-admission not only once but oftener if necessary to do a complete piece of work.

The physical condition of these 705 children on admission showed wide variations but all showed by x-ray definite evidence of tuberculous

infection. Two hundred and twenty-nine were manifestly in excellent condition in every way, 292, while well-developed, showed some signs of being undernourished, 91 were below par both in development and nourishment, while 68 were distinctly poorly developed and nourished. On discharge, with the exception of a very small group who went home against advice or who were discharged for the infraction of rules, all showed definite improvement, a point well confirmed by subsequent x-rays. Likewise, our records show that 90 per cent of the children who attended the Preventorium school were promoted, including a large number who had not done well in public schools prior to their admission. It was gratifying to note how rest, good food and fresh air along with new and attractive surroundings, individual attention, kindness and patience, awakened in the child an active interest to study and to learn.

An important and indeed an essential part of preventorium work is done after the child has left the institution. This consists in seeing that each child is under adequate medical supervision and is not lost sight of after discharge. This is done through an after care worker, in our case a nurse highly trained in this field. She visits each child in the home, sees that it reports regularly to the clinic or elsewhere for examination, and, of far greater importance, she obtains the cooperation of parents and other members of the family so that the training received at the Preventorium is not dropped. One of her duties, a most difficult and yet vital one, is to see that the original source of the child's infection is either eliminated altogether or reduced to a minimum, a difficult but not an impossible task. The thoroughness and efficiency of our own after-care worker in this regard are shown by the fact that during this eleven-year period, out of 705 children only 29 cannot be traced, while only one has been known to have since died of tuberculosis. Nineteen children were admitted to sanatoria after leaving our Preventorium not because of the development of active tuberculosis but in the case of some as a preventive measure, beds in our own institution not being available, or with others because they had passed our age limit. At present, all but four of these have returned to their homes and to school in good condition. Two children out of 705 have since developed pulmonary tuberculosis and have had active sanatorium treatment. The following is the story of one of these.

This girl, twelve years old, was admitted to our Preventorium in very poor condition and remained 296 days, gaining twenty-two and a half pounds. After her discharge, she was admitted to a sanatorium day school near her home which she attended for three years. In

prolonged, benefits are continued at the rate of one half the regular pay until disability ceases or death occurs

One might imagine that accidents and the disability for work due to them would be encouraged and prolonged under such a generous plan of benefits. They are not if properly controlled.

The plan is administered by a committee of five executives of the Company, responsible to the President. The members of the committee are themselves employees of the Company and beneficiaries under the plan when entitled to its benefits. The committee has both legal and medical advice upon its problem. Its decisions, based upon consideration of all evidence, facts, statements, opinions, information and claims pertaining to each case, are made in good faith and are final. Its policy is, I am sure, a very liberal one and in doubtful or borderline cases, the benefit of reasonable doubt favors the employee.

Recitation of a single case will serve as an example of the Company's policy in doubtful cases of accidental injury. A telephone pole broke off at the ground carrying a lineman working upon it to the ground with it. He landed in such a way that he acquired a fracture of the right scapula. He was hospitalized and treated by a competent surgeon and he apparently made an excellent recovery in a reasonable time. He was said to have had no other injury. He was examined for return to work, had recovered practically normal shoulder motion, had no symptoms of illness or disability, but was found to have a cardiac murmur. He was assigned to sedentary work. A month later, he was reexamined in the routine follow-up, and was observed to have a little dyspnea. Upon inquiry, he admitted some shortness of breath. He was again hospitalized under the care of a very prominent internist. A diagnosis of aortic insufficiency was established. No evidence of vascular disease, or rheumatism, or lues could be detected or found in the history. Lues was reported as the most likely causative factor and the internist declined to say that the accidental injury or the fall could explain the cardiac defect. Medical literature, so far as known, does not support such a theory of cause and effect as seen in this case. Yet the Benefit Committee accepted the presumption that this heart was just at the beginning of systole when the man struck the ground with force sufficient to fracture his scapula and at the same time to damage or even rupture a cusp of his aortic valve with, thereafter, progressive failure until death. Accident disability and death benefits amounting to \$7142 and medical expense of \$952 were paid by the Company.

It is interesting to recall that, during the last fifteen years at least, and without the protection

afforded by the Workmen's Compensation Law and Industrial Accident Commissions, no employee has prosecuted a suit against the Company because of his injury or allegedly unfair treatment. In some instances, as in the State of Maine, hearings have been held in order that the Commission may fix the degree of permanent impairment. No ruling by any commission has been disputed by the Company or held to be unfair.

There have been not more than two cases in fifteen years where allegedly injured employees were obliged to appear in person before the Benefit Committee in an effort to prove their claims. That is evidence of the satisfactory manner in which doubtful claims have been ironed out and disposed of by an understanding, sympathetic and rational discussion of the problem between the employee, his supervisors and the Medical Department before the matter is passed upon by the Benefit Committee.

I mention these facts because they indicate, I think, that the employees as a body, are reasonably well satisfied that the treatment accorded them under the benefit plan is just and fair and liberal.

In order that statistics upon lost time may be properly understood, it should be realized that, especially for men, there is a great variety of jobs at which temporarily and partially disabled men may be productively employed during the period of their lessened capacity and to know that splendid cooperation is extended by the management, by the employment supervisors and by the workmen to the Medical Department in this placement work. In this respect, we are probably favored above those industries wherein the variety of jobs is limited and probably favored over the insurance carrier who is defeated in his effort to restore a convalescent man to work when work would expedite his recovery.

Whatever statistics I may quote upon the results of different methods of surgical treatment of injuries represent only the experience in our Company and should not be interpreted as our opinion upon the efficiency of any particular method of treatment.

We are assured that in so far as management, the employment and other supervisors and the safety organization are aware and can arrange it, all accidental injuries, major and minor, are reported because the way has been made easy.

And finally, bear in mind, please, that the statistics which I will show and quote have been compiled by a statistical department entirely separate and apart from our Medical Department.

Now permit me to show a graph of the accident experience or incidence in the New England Telephone and Telegraph Company during the past ten years.

The chart* is cumulative, month by month for

*Chart I

we fear, that is definite and clear. It will not be until we have made a study of a similar group of children who have been exposed to tuberculosis but who have *not* had any preventorium experience and training and find out what has happened to them, that we can come to any justifiable conclusion as to the value of preventorium work. Certain facts, however, stand out, one especially, that out of 705 children exposed to tuberculosis and infected with that disease, only one child during a ten-year period has died of tuberculosis and only two have developed it in active or clinical form. There is the

fact, moreover, intangible but none the less evident, that the standards of living, health and happiness, not only of these children but of their families, have been markedly improved as a result of what these children have learned by example and by teaching at the Preventorium. This alone, we believe, fully justifies the money, energy and time spent on this work. On the whole, as a result of this ten years' study we are confirmed in our belief that the Preventorium is worth while and should be continued and is deserving of liberal support from the medical profession and the public.

THE MANAGEMENT OF INDUSTRIAL ACCIDENTS AFFECTING THE EMPLOYEES OF THE NEW ENGLAND TELEPHONE COMPANY*

BY D. L. LYNCH, M.D.†

MY first desire is to thank your secretary, Dr. William A. Rogers, for his kindness in inviting me to appear before you to-night. I regard it as a very great privilege.

It seemed to me that you might like to see, to look at or look down upon a so-called "Industrial Surgeon" or "Company Doctor", one of a group of probably normal men, much talked about and talked over, generously written up while unfavorably written about, criticized and even maligned, yet quite misunderstood, I am sure. We differ from you only in that our efforts and our services are devoted almost wholly to a special group of working people. We endeavor always to respect the rights and privileges of private practitioners and their patients.

It seemed to me, also, that it might be of interest to you who are particularly concerned with the treatment of accidental injuries to see what results may be achieved in the control of the accident problem in industry when management and workers together attack the problem sincerely and seriously, when the industrial surgeon is a part of the picture and when workmen's compensation laws, industrial accident commissions and other of the usual forms of compensation and insurance and their carriers are not a part of the picture, in other words, when the workers in an industry, executives and workmen together honestly endeavor to control both accidental injuries and compensation.

In order that my paper may be correctly interpreted, I wish to make a few introductory statements.

For many years I have had the honor of being associated, as a physician, with the New England Telephone and Telegraph Company, a

part of the Bell System. As surgeons who may have been or who yet may be called upon to care for an injured employee and very likely as holders of the Bell System's securities, you are undoubtedly interested in the affairs and successes of the Company.

The Company operates throughout all of New England except in Connecticut. It employs, on a yearly average, approximately 20,000 men and women. Our Medical Department is concerned in all the accident and health problems of this group of people throughout the territory.

The Company is a so-called self-insurer. Since January 1, 1913, it has maintained a non contributory plan for employees' pensions, accident and sickness disability benefits and death benefits. In the states where the Industrial Accident Act or Workmen's Compensation Law is not compulsory, as in Massachusetts, the Company cares for its injured employees under this benefit plan. Accident benefits under the plan are greater than compensation under the law. In other states, the Company has been privileged by the various industrial accident commissions to substitute the plan for the act, again because its benefits are the greater.

It is very important in this connection and when viewing our statistics on accident disability and lost time and compensation, to know of the greater benefits under the benefit plan than under the compensation law. There is no maximum payment under the plan. Any employee of the Company disabled by an accident arising out of and in the course of employment is entitled to benefits at the rate of his full pay, whether it be \$20.00 or \$50.00 or \$100 per week from the very first day of such disability for a period of thirteen weeks. That period is usually sufficient to restore the employee to some kind of work. Should disability, however, be

*Read before the Boston Orthopaedic Club November 13 1933.
†Lynch, D. L.—Medical Director New England Telephone & Telegraph Company. For record and address of author see This Week's Issue page 1344.

to avoid the death. We regret every one of them. That so many occurred will convince you, I am sure, that the work in which our men are engaged is not altogether free from hazards making for serious accidental injuries.

I am confident that this group of statistics substantiate my previous statement that the

would have caused lost time from work. It is not because injured men unfit for work have been required to work, but rather because education, mental hygiene, and pride in their performance have improved the whole attitude of these men toward the problem of accidents. When men who would otherwise lose their pay

CHART III

liberal accident disability benefit plan of the Company has not encouraged lost time due to accidents.

I have heard it said that lost time accidents are reduced in number, to some extent at least, because the "hard-boiled industrial surgeon" requires injured men to work who should be at rest at home. That is not so. If it were true and if practically all accidents are properly reported, as I am assured, the number of *no lost time* or minor accidents should be affected, either increased, or stabilized. Let's examine the record.

Section 2 of Chart III reveals that *no lost time* or minor accidents involving Plant Department men have declined from 3576 in 1924 to 831 thus far in 1933. It represents a reduction of 76.5 per cent in the number of minor accidents.

Unquestionably, the count of minor accidents in the recent years includes cases that earlier

will report for work in spite of a minor injury acquired at home or at play, lost time from the same or similar injuries acquired at work must stop if the men are as fair and reasonable as telephone men.

Chart III also reveals, in the third section, the number of calendar days lost from work each month and each year by reason of disabling accidents. It shows that the number of such days progressively decreased from 9203 in 1924 to 1347 for nine months of this year, a decrease of 85.4 per cent. And so the trend of lost time has been definitely downward, indicating a decrease in the severity as well as in the number of accidents.

But this tabulation of lost days is deceptive. It does not follow that because there have been only sixteen disabling accidents involving our men and 1347 lost days that the severity rate was eighty-five days. That would indicate severe injuries and prolonged disability. The fact is that

each year. Notice the monthly step-up from January to December in 1924. In that year there occurred a total of 583 lost time or totally disabling accidents. Of this number, 454, represented on the chart by the heavy black dots, occurred to workmen in the Plant Department, the men who perform manual work and who encounter real hazards above the ground on poles, ladders and buildings, on the ground in congested streets, in automobiles and trucks, in

the number of men has been reduced during the recent four lean years of depression.

Chart II shows the accident experience upon a ratio or frequency basis. It reveals a consistent drop from 4.43 accidents per 100 men in 1924 to 2.25 per 100 men during the nine months of this year. And our men have been doing the same manner of work throughout the decade.

Chart III, in its upper section, reveals numerically the accident experience shown graphically

CHART I

basements and dark cellars and below the ground in manholes and trenches. The remainder of the total number involved supervisors and office workers, chiefly young women telephone operators.

Note that there has been a progressive, almost steady decline in the number of accidents among both groups of employees during the ten-year period and that for nine months of the current year, the total has dropped to 70, of which only 16, represented by the heavy dots, occurred in the group of nearly 7000 Plant Department men. That represents a decrease of 96.4 per cent in serious accidents among men in the past ten-year period.

I like that chart because it reveals more than a numerical reduction in serious accidents. It visualizes for me the cooperative spirit and effort of management and men to eliminate the pain and the suffering and the anxiety that follow on accidents and to enable these men to return home from work uninjured and unimpaired.

Now it may be imagined or even suggested that the number of accidents declined because

*Fatal Cases

CHART III.

liberal accident disability benefit plan of the Company has not encouraged lost time due to accidents

I have heard it said that lost time accidents are reduced in number, to some extent at least, because the "hard-boiled industrial surgeon" requires injured men to work who should be at rest at home That is not so If it were true and if practically all accidents are properly reported, as I am assured, the number of *no lost time* or minor accidents should be affected, either increased, or stabilized Let's examine the record.

Section 2 of Chart III reveals that *no lost time* or minor accidents involving Plant Department men have declined from 3576 in 1924 to 831 thus far in 1933 It represents a reduction of 76.5 per cent in the number of minor accidents

Unquestionably, the count of minor accidents in the recent years includes cases that earlier

will report for work in spite of a minor injury acquired at home or at play, lost time from the same or similar injuries acquired at work must stop if the men are as fair and reasonable as telephone men

Chart III also reveals, in the third section, the number of calendar days lost from work each month and each year by reason of disabling accidents It shows that the number of such days progressively decreased from 9203 in 1924 to 1347 for nine months of this year, a decrease of 85.4 per cent And so the trend of lost time has been definitely downward, indicating a decrease in the severity as well as in the number of accidents

But this tabulation of lost days is deceptive It does not follow that because there have been only sixteen disabling accidents involving our men and 1347 lost days that the severity rate was eighty-five days That would indicate severe injuries and prolonged disability The fact is that

lost days are carried forward from month to month and year to year from the day of each accident as long as its resulting disability continues. Thus the figure of 1347 includes lost days in 1933 by men who were injured in 1932, in 1931 and in 1930.

I regret that there is a feeling prevalent among medical men that we "industrial surgeons" transgress the rights of private physicians by treating many industrial accident injuries. Again, I fear that some surgeons have felt that their work, or what they formerly did for industry, has been lessened or detoured by the company doctor who shunted injured men to his personal or intimate friends.

Of course I can speak only for my department, but I submit that the three charts I have shown make such ideas out to be utterly false. The fact is, as you can plainly see, that the volume of work no longer exists for anybody to do.

If similar conditions prevail in industry generally, I am confident that you will agree that we fellows did not steal your business. It simply isn't there.

It is true, that the "industrial surgeon" has played a part in reducing the number and in minimizing the severity of accidental injuries. But surely he should not be criticized or condemned because he has tried to prevent needless human suffering. You all do that very thing just as often as you can.

The story behind this satisfactory accident experience would take too long for telling. Suffice it now to say that it is the result of teamwork between the management of the Company, the safety and first aid organization, the employment supervisors, the workmen's organization (the International Brotherhood of Telephone Workers), the improved attitude of the workmen themselves toward the problem, and the Medical Department.

The medical contribution consists chiefly,—

1 In the examination of applicants for work wherein an attempt is made to select the proper type of man for the job specified.

2 In follow-up examinations to be assured that newly engaged men have overcome the correctable impairments detected at the pre-employment examination.

3 In a thorough examination, physical, neurological and not infrequently mental of employees who have been injured, followed by a work reassignment of the man whose uncorrectable impaired condition caused or contributed to the accident.

4 In the examination of employees who have been absent from work for seven days for any health reason. Such examinations are, generally speaking, more fruitful than periodic health examinations.

5 In the examination of employees observed or properly suspected by their supervisors or

by the safety organization of being careless or in an unsatisfactory health condition.

Such examinations are frequently exhaustive, and may include a test of vision, a neurological check-up, frequently x-ray, and almost always a blood Wassermann. Not infrequently they delve into the social condition to uncover possible psychological causes of accidents.

6 In the periodic reexamination and encouragement of employees who have been seriously injured until they admit recovery and for an extended period thereafter.

7 In the insistence by the Medical Department, in so far as possible, that the injured employee remain with or under supervision by the doctor who first cared for the injury. Experience indicates that the migratory patient does badly and the variety of opinions and advice that he picks up delay his progress as barnacles slow down a ship.

8 In a policy of definite but sympathetic firmness that an injured employee must return to work within his capacity as soon as he is able, or at once if the injury is not severe, because it is good for his mental health, for his morale and for the morale of his home. This policy of the Medical Department has been made workable by the splendid cooperation of the employment supervisors, who have found ways and means to place such employees, usually productively. It cannot but prevent many neuroses.

9 In the instruction by the safety organization of all male employees in adequate first aid to the injured. The American Red Cross has awarded certificates for first aid to upwards of 7000 men of the Company. Immediate adequate first aid cannot but minimize the severity of many injuries. We have not had in Boston a real septic hand for five years.

10 In what we believe to be prompt and adequate examination and treatment by or under the supervision of our Medical Department for the majority of accidental injuries.

If these practices of industrial medicine have contributed anything toward the reduction in the number and in the severity of accidents, we are glad of it, and we know that it is unjust to censor us even though the volume of work for private practitioners may be lessened.

Chart IV is an illustration upon an employee ratio basis of the yearly reduction in serious and lost time accidents involving both men and women employees during the last decade. It indicates a progressive reduction during that period for men, for women and for the total of the two groups from 22 per 100 employees in 1924 to 4 per 100 employees in 1933.

Chart V may be of particular interest to those of you who are especially concerned with compensation. It is my understanding that coverage in industry is based upon the hazards involved and upon a percentage of the payroll. I do not know whether Mr. Parks and Mr. Mars-

ton would consider the percentage of Company payroll in this instance, which includes all compensation paid to injured employees and all expense for treatment high or low. I show it because I think it is interesting. It shows a progressive reduction in accident expense from \$85,925 in 1924 to \$21,804 this year. In my opinion, it is a favorable showing. It shows a

CHART V

drop in per cent of payroll from 2.6 in 1924 to 1.0 this year.

The chart shows something else that is very interesting, that is, treatment expense, or the sums paid to private doctors, dentists, hospitals, nurses, etc., for the treatment of injured employees.

Please note that in one year such expenses exceeded the sum paid to injured employees, that it closely approached it elsewhere and that it has always been relatively high. Please bear in mind that the sum in any year may include an expense incurred in a previous year but delayed in billing and that an average cost based on the yearly number of cases is not justified.

I wish now to lay particular emphasis upon the fact that our Company has no quarrel with

doctors' bills that apply to legitimate accidents. I have the privilege of approving these bills for payment, and I have nothing but respect for the fairness with which charges against our Company are made. Seldom is the Company used as a Christmas tree, and I can recall only four medical bills in fifteen years that were disputed. I can recall a greater number where we felt it proper to tell the doctor that he was cheating himself, that the employee's condition and recovery entitled him to a greater fee, and that he could and should increase his charge.

Of course it has happened, and it probably will occur again, that a particular bill cannot be paid by the Company because the Benefit Committee is unable to find that the treated employee's condition was the result of an accident arising out of and in the course of employment. I repeat what I said before, that the policy of the Benefit Committee for the Company is a liberal one but it is not wasteful, nor does it accept extravagant claims. It rejects them. Unfortunately, the doctor concerned in such a case is acquainted only with the patient's story, not with all the facts, and unfortunately, too, feels hurt when the Company fails to pay up.

I am confident that medical charges under the Workmen's Compensation Law would be less annoying to all concerned if all the bills could be passed upon by a medical person able to visualize the character and extent of injury, the type and extent of surgery and treatment involved, to appreciate the purpose of doctors generally to do the right thing, and to realize that peace of mind for the injured person is essential to recovery. Scolding and quarrelling about a medical bill, even a hospital private room fee or an extra visit, does not help the patient to get well.

We realize that our injured fellow workers should have adequate and really good medical service and we feel that they get it. The Company is willing to pay accordingly when the accident is bona fide.

I have in mind a surgeon's bill for \$750 for two laparotomies upon an injured employee which we were glad to pay. The man recovered and eventually resumed his regular work.

I have in mind a medical expense of \$5966.87 incurred and paid on account of a lineman who alleged that a month before he developed a subpectoral abscess, he acquired a splinter under his thumb-nail while at work.

Chart VI lists a limited number of vertebral body fractures, compression fractures that occurred in a five-year period, and indicates the number of calendar days lost from work in each case. There is a total of ten cases arranged by the number of calendar days lost from work in each case. The average lost time per case was 122.2 days.

All of them were treated conservatively. All of them, except No 10, were treated either by a member of our medical staff or by a selected orthopedist. The compression fracture in No 4 was complicated by a serious hypertension, in No 8 by a fractured os calcis, in No 7 there were two separate fractures, a cervical and a lumbar, No 6 had been operated upon for carcinoma of the tongue sixteen months earlier. He did not have a metastasis in the spine, thank

CHART VI

Heaven. He is to day apparently well. No 9 was complicated by an annoying deficiency disease, and we purposely delayed his return to work. No 5 is a man of most peculiar and suspicious make-up, and we were fortunate to return him to work when we did. Otherwise, I am afraid he would be permanently disabled. He remains steadily at work.

In case No 3, occurring in a distant city, the orthopedist who instituted treatment proposed a fusion. That operation has not recommended itself to us, and we interfered, preventing it. Apparently the man made a good recovery from his accident, now three years past, and returned to work. I saw him a month ago and he is in good condition.

I wish here to thank Dr. William A. Rogers, and also Dr. B. A. Godvin, of our staff, for these results.

I do not wish to imply that these injured men upon their return to work immediately resumed full duty as linemen or cable splicers, or what not. I mean that they returned to gainful occupation, to a daily routine, in an average of 122 days, thus avoiding neuroses, psychoneuroses, defeatism and all the other mental ills that result from prolonged idleness.

It is our policy to decide against line work or the climbing of telephone poles when a man has had a fracture of a vertebral body. Generally, however, these men prefer to return to that work and eventually do so. No 8, in spite of his fractured vertebra and os calcis, is climbing telephone poles, and No 7, in spite of two fractures, is climbing telephone poles.

Since January 1, 1932, we have encountered 126 allegedly injured backs without fractures

among our Plant men. These injuries resulted from falls, long and short, strains in lifting or pulling, or other exertions, blows from falling or swinging objects, automobile accidents, etc. They include the usual types of muscle and lumbosacral and sacro-iliac strains. Many of them were unimportant, some of them were mild, some of them were not injuries in reality, but rather lumbago or other evidences of arthritis and one was of pain due to a large stone in the kidney. Out of this number of 126 allegedly injured men, only three men have lost any time from work, one for forty days, one for nineteen days, and one for twelve days, an average lost time of twenty-four days per case for that group. It is true that a number of these men were temporarily placed upon limited or restricted duty, but they were kept occupied, and I am sure they felt better and were better for it.

We do not suggest that a similar performance is to be expected immediately from all men everywhere reporting back strain. It takes time and example to convince them of the benefit of some form of occupation as good therapeutics, it takes time and patience to mould their psychology favorably, and we doctors must learn from such performances that not every alleged or trivial back strain requires or justifies adhesive strapping and a long rest. If we can do our work in spite of a little backache, our patients should do likewise.

Time did not permit me to tabulate the total number of back injuries to women in the Company since January, 1932. Of course we have many such injuries because telephone girls will slip on waxed floors and trip over their telephone cords and they will fall downstairs.

I have, however, a record of ten, all the back injuries in women that caused lost time since January, 1932. The longest period of absence was twenty-nine days, the shortest one day, and the average fifteen days. They were the usual run of cases and our staff, generally Dr. Godvin, treated most of them.

About three years ago, a young woman who slipped on a tiled floor fell and apparently received a sacro-iliac strain. She had her private physician who notified us that he was through with the case within a month because he believed that she exaggerated her symptoms. We attempted to help her but soon found ourselves defeated when we discovered that she was being advised and controlled by a nurse. We lost patience with her, I am sorry to say. She employed a private surgeon. She had a fusion two and one-half years ago, and she has made no progress whatever toward recovery of working ability. She still complains of pain in the back. I repeat that the operation of fusion has not recommended itself to us.

May I now show you on the last chart No

VII, the result of treatment in nine accidental injuries resulting in fractured ossa calces. These men fell or jumped from telephone poles or from a staging.

FRACTURES OF THE OSSA CALCIS

Arthrodesis		Manipulation and Impaction

Average per case	246	Average per case	124

CHART VII.

Nos 1, 2, 3 and 4 were treated privately, either because they reported immediately to a private physician or were removed to a nearby hospital. This group was treated by open operation. The average days lost per case were 246.

Nos 5, 6, 7, 8 and 9 were similar cases in which we were able to institute or engage treatment. None of them had open operation, rather they had manipulation and impaction under ether. No 5 had fractured both ossa calces, No 9 had fractured both ossa calces, both men falling from telephone poles, and No 8 also had a vertebral compression fracture. The average days per case lost from work in this group were 124.

None of the first group of men have ever been able to return to work as linemen. Four of the second group are climbing and I hope the last one, a fairly recent case, will be able to do so.

Of course, no two fractures may be exactly alike and the same treatment may not be best suited for all cases. But a fractured os calcis is a fractured os calcis and you may take this picture for what it is worth.

It was my feeling that injured backs and fractured heels would interest you. Whether our management of these annoying problems is good or bad as compared with the results obtained by other men, I do not know. I told about them because they are problems, but I do know that no telephone man who had a fracture in his spine or who strained or otherwise injured his back or who broke his heels is permanently disabled for work, or ever was pensioned or fired from work, because of incapacity or of inability to do some work. And with only two exceptions, all telephone men who have ever been injured by reason of an accident arising out of and in the course of employment and who survived are earning to-day as much as they did before the accident or more. Only one man is perhaps permanently disabled. He was past sixty-two years of age and had Parkinson's disease when he slipped on a stairway without physical or serious injury, but his preëxisting pronounced disability was considered aggravated by the fall. That is liberal treatment of a high order.

Only two women who have been injured within the last twenty years failed to return to work. One of these has been disabled for four years. She is a mental problem. The other is the sacro-iliac case, now absent from work thirty-five months. I hope they, too, will recover working ability.

Such, then, are the results, good or bad, of an experience wherein the problems of industrial accidents are controlled by the industry itself and when education, fair and just treatment have developed cooperation, right thinking and a helpful responsive attitude on the part of the employees of that industry.

ARTIFICIAL LIGAMENTS AT THE KNEE

A Technique

BY FREDERIC JAY COTTON, M.D.,* AND GORDON MACKAY MORRISON, M.D.*

RUPTURES of lateral ligaments or ruptured crucials at the knee have engendered a vast deal of literature.

*First, as to the ruptured crucials, the diagnosis is at least difficult, and with even one lateral gone there is enough free play to make the crucials suspected. There is a good deal of reason to feel that with the laterals intact or restored, perhaps ruptured crucials may not be very important. Then, too, any direct attack on the crucials must do some harm and be of doubtful mechanical stabilizing effect.

Of the indirect methods only Galie's ingenious use of the gracilis tendon commends itself. There are a number of other schemes mechanically doubtful, seemingly without much record of success. The technique here described is the outcome of a long-cherished conviction that the important item was restoration of laterals, strong enough to hold and so placed as not to lock motion in flexion and extension.

The first case, about twenty years ago, was one of a loose knee following a total dislocation. The patient was a middle-aged man. The suture material was heavy braided silk.* Later, partly

*Under the influence of Professor Dr. Lange we were using silk at that time for everything for bridging of an interval, expecting repair to convert the silk into a scar tendon. Sooner or later we got back most of this silk.

All of them were treated conservatively. All of them, except No 10, were treated either by a member of our medical staff or by a selected orthopedist. The compression fracture in No 4 was complicated by a serious hypertension, in No 8 by a fractured os calcis, in No 7 there were two separate fractures, a cervical and a lumbar, No 6 had been operated upon for carcinoma of the tongue sixteen months earlier. He did not have a metastasis in the spine, thank

That is liberal treatment of a high order.

Only two women who have been injured within the last twenty years failed to return to work. One of these has been disabled for four years. She is a mental problem. The other is the sacro-iliac case, now absent from work thirty-five months. I hope they, too, will recover working ability.

Such, then, are the results, good or bad, of an experience wherein the problems of industrial accidents are controlled by the industry itself and when education, fair and just treatment have developed cooperation, right thinking and a helpful responsive attitude on the part of the employees of that industry.

ARTIFICIAL LIGAMENTS AT THE KNEE

A Technique

BY FREDERIC JAY COTTON, M.D.,* AND GORDON MACKAY MORRISON, M.D.*

RUPTURES of lateral ligaments or ruptured crucials at the knee have engendered a vast deal of literature.

*First, as to the ruptured crucials, the diagnosis is at least difficult, and with even one lateral gone there is enough free play to make the crucials suspected. There is a good deal of reason to feel that with the laterals intact or restored, perhaps ruptured crucials may not be very important. Then, too, any direct attack on the crucials must do some harm and be of doubtful mechanical stabilizing effect.

Of the indirect methods only Gallie's ingenious use of the gracilis tendon commends itself. There are a number of other schemes mechanically doubtful, seemingly without much record of success. The technique here described is the outcome of a long-cherished conviction that the important item was restoration of laterals, strong enough to hold and so placed as not to lock motion in flexion and extension.

The first case, about twenty years ago, was one of a loose knee following a total dislocation. The patient was a middle-aged man. The suture material was heavy braided silk.* Later, partly

*Cotton and Morrison—For records and addresses of authors see page 817 issue of April 12, 1934.

*Under the influence of Professor Dr. Lange we were using silk at that time for everything for bridging of an interval expecting repair to convert the silk into a scar tendon. Sooner or later we got back most of this silk.

because of the irritation leading to removal of the silk, there was a good deal of loss of motion though the joint was stable

The principle of the x-suture deeply placed was made clear, however, and presently we were doing occasional cases with the present technique, using fascial bands. The essential thing about it all is that with one or both laterals gone, satisfactory ligaments may be constructed out of fascia

To avoid interference with motion the resultant ligament must be attached near the radial center of the curve of the femoral joint surface, seen laterally (see figure) just below the tip of the adductor tubercle, if we are making

an internal lateral ligament and not too far back or front at the tibial attachment. To get strong bony mooring the fascial strip must go deep under a strong bridge of bone rather deep into the cancellous bone. That means two holes and, in order to avoid an undesirable broad ribbon of ligament, it means an x-crossing of the false ligament. The fascia is drawn taut, knotted, and the knot fastened with gut or fine silk sutures. The whole operation, even if both inner and outer sides are operated on, can be done without opening the knee joint. There is no point in opening it.

Motion at three weeks, weight at six, gives results. A convalescent splint will be called for longer than this, because there is, no matter how tight the knot, a slacking up of the ligament

This slack "takes up" with time but is likely to persist for four months or more

Two cases had poor motion.*

The rest of the not long list recovered satisfactory function though with less than normal range of flexion

J M, aged 21, seen October 3, 1929. Was running down the field in a football game when his knee gave way. This was three months before he was examined. He showed unquestioned rupture of the external lateral ligament (including the long lateral) of the right knee, with marked abnormal mobility, unimproved in the three month interval.

Operation was performed at the Boston City Hospital, November 7, 1929. This was the typical insertion of a suture of strong fascia from the thigh, passed under a bridge of cortical bone above and below the joint, and crossed in x pattern and tied as already described.

Recovery was satisfactory, with no trouble after the early part of the year 1930. Has played baseball, tennis, etc. Examined July 11, 1933. He showed full motion of the knee, no abnormal "slack" laterally, and demonstrated that he could squat on his heels, and do the "duck waddle."

There is some risk of mistake as to the diagnosis of ligament rupture, and several cases have been seen which were diagnosed as internal lateral ligament tears in which operation disclosed an intact ligament, but sharp tearing of the stout fascia enclosing the insertion of the vastus internus, and the hamstrings. All did well, but might have done well without operation. Oddly enough these cases may show an abnormal lateral mobility of twenty degrees or more.

Case S W, aged 30. Seen in consultation at the Boston City Hospital, January 13, 1930. Five days previously he had sustained a compound fracture of the right ankle, an injury to the left brachial plexus and damage to the right knee without gross lesions. Seen again January 21. At that time a gap could be felt in the tissues on the inner side of the knee, abnormal lateral motion persisted, but operation was recommended for tear of the fascia, not the ligament.

Operation at City Hospital, February 4, 1930. Oblique tear in the fascia in front of the hamstrings two inches long. This was sutured. March 17 note "knee solid, motion returning." As late as the spring of 1933 he was entirely without trace of any of his injuries.

*But both had had total knee dislocations though without much damage.

A CALL FOR HELP

There are four sources of illness, suffering, and annoyance which the Board of Health is trying to eliminate during the summer months for the benefit of our residents. The effectiveness of this work depends largely on the help and coöperation which we receive from our residents. The activities to which we refer are the prevention of fly and mosquito breeding and the destruction of ragweed and poison ivy. The prevention of fly breeding and the destruction of ragweed and poison ivy are considered in detail in special articles in this issue of the *Bulletin*, which our citizens should read in order to learn how they may help in this work.

Mosquito control has been repeatedly discussed in previous issues so we will merely emphasize at this time the fact that mosquitoes breed only in water. Any water that stands for ten days may be a source of mosquito breeding. Hundreds of mosquitoes may emerge from an ordinary tin can which is left around the yard, from a watering pot or pail, and other chance receptacles. The inspectors locate many of these but they cannot get around often enough to keep everyone's place free from standing water, so that we must depend largely on our citizens to prevent mosquito breeding.—*Brookline Health Bulletin*

MEDICAL PROGRESS

PROGRESS IN ANESTHESIA IN 1933

BY RUSSELL F. SHELDON, M.D.*

At its 1933 session in Chicago the American Medical Association devoted two days to Anesthesia. An anesthetist, Albert H. Miller, Providence, R. I. was Chairman of the Section on Miscellaneous Topics, and presided at these meetings. In addition, further steps were taken during 1933 toward the national certification of specialists in anesthesia and more active measures have been taken, both in legislative and medical channels to clarify the status of the physician anesthetist. But most significant of all at least locally, more serious efforts are being made in the instruction of students in the art and practice of anesthesia. There is particular reference to the changes made in this respect at the Harvard Medical School, and in connection therewith to the appointment of a resident anesthetist at the Massachusetts General Hospital.

Locally, and throughout the country, anesthetists mourn the loss on November 16, of their esteemed confrere, Frank L. Richardson.

The literature of 1933 is as usual prolific, and no attempt at listing all of it will be made. The enthusiasm which accompanied the introduction of barbituric acid derivatives has somewhat abated, though the use of one new product, sodium evipan^{1, 2, 3, 4, 5}, as a brief intravenous general anesthetic agent has attained considerable publicity. But in general, the barbiturates have proved more useful as preliminary sedatives⁶ than as anesthetic agents in themselves. Certain other new ones have been presented.⁸

In a similar way the rectal use of trihromethanol is becoming more of a preliminary to inhalation or local methods than for complete anesthesia. Authentic reports on fatal cases following the use of avertin are still scarce^{9, 10, 11}, though occasional authors, as Evans¹², speak of them as occurring. Barlow^{13, 14}, has continued his researches to include the study of avertin fluid, as marketed, with amylene hydrate as solvent, and concludes that the presence of amylene hydrate delays the absorption of trihromethanol, and therefore makes it safer. These studies were made on the rat, but are probably applicable to human beings. Koontz and Moulton¹⁵ present an interesting study on the effect of avertin in the treatment of lung edema brought on by chemical irritation, as in gas warfare, or civilian practice as exemplified by the Cleveland disaster. They find it to be

of distinct benefit. As a more accurate test than the usual Congo red for the purity of avertin fluid preparatory to use, Ashworth¹⁶, recommends the use of "Universal indicator."

In inhalation anesthesia two new agents have been introduced, divinyl oxide, commercially vinesthine, prepared by Merck, and cyclopropane. The latter is still undergoing tests of its usefulness and application, and has not yet appeared to any great extent in the literature. It is, however like divinyl oxide, originally a creature of the chemist, a product which in theory ought to be a good anesthetic. The results of intensive clinical application by Waters at Wisconsin will later be available. Its originator is Henderson of Toronto.

Divinyl oxide, put forth by Leake¹⁷ in California, has been tried out in animals and to some extent in human beings¹⁸. In theory it should be an ideal anesthetic, but in action it approximates chloroform. Its general use is not yet indicated.

Herb¹⁹ maintains her position on the superiority of ethylene for general anesthesia. She reports as shown by answers to a questionnaire, thirty-nine explosions with seven injuries and five deaths from nitrous oxide, oxygen and ether, and twenty explosions with one injury and five deaths from ethylene, and with mixtures of nitrous oxide and ethylene two deaths. Sise²⁰ also finds more explosions with nitrous oxide, oxygen and ether than with ethylene. Humidity of the operating-room appears to be the safety factor in the prevention of explosions.

In its report for 1932²¹, published in 1933, the Mayo Clinic reports an increase in the use of ether. This trend is, I believe, noticeable in other places.

Spinal anesthesia, despite the crepe-hanging of Landemulder²² maintains its popularity, especially for genito-urinary and pelvic work and surgery of the lower extremities. Marvin²³, Kemp²⁴, Grodinsky²⁵, and Tovell²⁶ provide sensible and clear presentations of its scope and usefulness. In nomenclature, neothesis has become metvaine.

The Mayo Clinic²⁷ finds the use of ampoules of ten per cent solution of procaine more convenient and less expensive than the crystals the use of which has been discontinued, but elsewhere the crystals maintain their lead. Harpin²⁸, emphasizes the value of caudal anesthesia in urology, and Dogliotti²⁹ presents a full description of the peridural technique.

Little new in technique has been brought out,

Sheldon, Russell F.—Assistant Anesthetist, Massachusetts General Hospital and Massachusetts Eye and Ear Infirmary. For record and address of author see "This Week's Issue" page 1344.

but there is definite increased use of the carbon-dioxide filtration method, and for upper abdominal work, administration of volatile anesthetics by the intratracheal route has increased. This of course insures an airway, and to lessen the trauma from metallic pharyngeal airways Guedel⁵⁰ has introduced a non-traumatic one made of rubber.

Flagg^{31 32 33} has kept up his campaign against asphyxial deaths, and urges cooperation of all agencies concerned, fire departments, public service corporations, and above all, the medical profession.

In resuscitation, Wood³⁶, Killian³⁴ and Reese³⁵ proclaim the virtues of coramine and in the use of hydrochloric acid intravenously MacGillivray³⁷ has introduced the term palmaesthesia. Further investigation, however, is needed in both these drugs.

In research, the Massachusetts General Hospital^{38 39 40 41} has contributed some valuable work under the leadership of Means and Churchill. The physiology of respiration with the open chest and abdomen has received intensive study. At Wisconsin, Orcutt and Waters⁴² have shown the diffusibility of nitrous oxide and ethylene through human skin. Further experimental work on spinal has been published from the Mayo Clinic^{27 43 44} and Co Tu⁴⁵ and Hill and Macdonald⁴⁶ have continued their studies. The so-called circulation of the cerebrospinal fluid has been investigated by Hassin⁴⁷, and, further, Bhatia and Burn⁴⁸ have reported on the action of ether on the sympathetic nervous system. Neff⁴⁹ finds the present ether as supplied by the manufacturers to be generally pure but does not recommend its standing more than forty-eight hours in a gas machine.

In the estimation of the preoperative risk and the prophylaxis of postoperative complications in surgery of the biliary tract, Hussey⁵⁰ summarizes the available information, and McQuiston⁵¹ shows that hypotension in itself is not a serious factor.

Constant efforts in oxygen therapy are producing new and better tents.

Studies in postoperative complications, especially pulmonary, continue, but no new startling conclusions have appeared. King^{52 53 54}, however, remains in the minority as regards the value of carbon dioxide in the prevention of pulmonary complications. Alison⁵⁵, Prinzmetal, et al⁵⁶, and Bergh⁵⁷ feel that inhalations of carbon dioxide are helpful. Overholt and Veal⁵⁸ show that certain chest conditions may be "normal" after surgical procedures. Coryllos⁵⁹ describes his technique of intratracheal anesthesia and bronchial suction as helpful in the prevention of complications in the surgical treatment of tuberculosis.

For 1934 anesthesia looks forward to a continued advancement to the end that benefits will accrue to both patient and surgeon.

JUST ANOTHER PROOF

In the Journal of the American Medical Association of October 28, 1933, Clausen, S W and McCoord, Augusta B, make the following statement "Under ordinary circumstances sufficient quantities of Vitamin A are provided by a diet in infancy which contains milk, cod liver oil from the second week of life, and vegetables from the fifth or sixth month "

Just another proof that many of the foremost investigators regard cod liver oil as the good, old reliable, and that it no doubt will continue to be prescribed after many of the new-fangled vitamin fads and artificial substitutes have fallen into disrepute

The story of Patch's Cod Liver Oil is now, as always, straightforward, ungarnished

First, Patch's Cod Liver Oil is guaranteed, tested in terms of both potency and purity

Patch's Cod Liver Oil overcomes the one possible objection. Patch's is flavored and palatable

Whoever says he does not like cod liver oil, we will be glad to send you a complimentary sample so that you can get him

CANCER MORTALITY

Decrying the difficulty of obtaining accurate information respecting cancer mortality due to the fact, among others, that in a number of states the disease is not reportable by law, Dr Louis I. Dublin on May 25 urged cancer specialists and the entire medical profession to cooperate with vital statisticians in an effort to secure more reliable data along these lines.

In an address on the "Incidence of Gastric Cancers" before the Symposium on Carcinoma of the Stomach, at the fiftieth anniversary of Memorial Hospital, Dr Dublin presented statistics and facts pertaining to cancer of the stomach based upon the experience of his company's Industrial policyholders. He concluded that, in the United States, the stomach is the principal site of fatal cancer among white males and also very probably among white females that the incidence of gastric cancer is approximately fifty per cent greater among white males than among white females and that among white females, the death rate from gastric cancer and by inference the incidence of gastric cancer, appears to be decreasing at a rate greater than can be attributed to chance alone. 'Among males,' Dr Dublin said, "the death rate has shown a slight tendency to increase but this is statistically significant only at the older ages of life."

He said that 'possibly as many as one-third of the deaths actually due to cancer of the stomach are ascribed to other causes.'

Pointing out that in 1932 a total of 27,000 deaths from gastric cancer were recorded for the population of the United States, he declared that 'it is my judgment that instead of 27,000 the annual number of deaths from cancer of the stomach and duodenum in the country at large is now more likely to be close to 40,000, or about as many as

from bronchopneumonia, or coronary disease, including angina pectoris."

The statistical picture, however, Dr Dublin declared is improving.

"I give you these figures for the insured with the very strong conviction that they show us essentially what has been happening in this disease in the general population of the country."

"There was a total of 40,573 deaths from gastric cancer among these insured lives in the years 1917 to 1933 inclusive. These occurred among an annual average of fifteen million policyholders over this period. The average annual crude death rate was, therefore 15.5 per 100,000 exposed. The gastric cancers constituted 20.8 per cent of all cancer deaths, the figures being much higher among the males than among the females."

He explained that deaths from gastric cancer are largely concentrated in the later ages of life.

"There are few deaths under 25. At ages 25 to 34, the rates are still low—averaging less than two per 100,000 per annum. It is only after age 35 that the death rate from this disease has any real meaning. At 45 to 54 years, the rates are already fairly high."

"Among white males the average death rate in this age group over this entire period of seventeen years was 46.7 per 100,000, as contrasted with 30.6 per hundred thousand among white females. The death rate almost trebles in the next age period. Among white males it is 132.7 per 100,000, among white females, 85.2 per 100,000. In the next age period that is, 65 to 74, the rate almost doubles among white males and more than doubles among white females. The interesting points in figures are first, that the rates rise with advancing age and, second, that they are much higher among the males than among the females, being, in fact from a third to a half higher in the white race."

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL PATHOLOGIC EXERCISES

EDITED BY RICHARD C. CABOT, M.D.
F. M. PAINTER, A.B., ASSISTANT EDITOR

CASE 20251

PRESENTATION OF CASE

First admission A sixty-one year old American widow entered for the first time eight months before her final admission.

Four months before admission she noticed a swelling on the left edge of her tongue. This swelling became sore and gradually increased to about one inch in diameter. She had worn a plate of false teeth in the upper jaw for eighteen years, and a few false teeth in the lower jaw. So far as she knew the plate fitted well and produced no irritation.

She had been seen in the Outpatient Department, where a biopsy showed an epidermoid carcinoma, grade III, and Hinton and Wassermann tests were positive.

There was no history of tuberculosis or cancer. She used no tobacco or alcohol.

The patient had been married for twenty-five years. Her husband died of heart failure five years before her admission. She had no children. She had had amenorrhea since the age of twenty-one. The cause of this was unknown.

She had had a cataract removed from her right eye nine years before admission. She had had severe frontal headaches, usually coming on in the evening. She had difficulty in hearing and occasional ringing in the ears. There was no history of precordial pain, palpitation, dyspnea or edema. She had pleurisy six years before admission, but no cough or hemoptysis.

Physical examination showed a well-nourished woman lying quietly in bed. There was a small cataract in the left eye, and the right eye showed an operative defect from the removal of a cataract. There was a large perforation of the bony septum of the nose. The lesion on the tongue was located on the left side and extended from the anterior pillar of the fauces halfway to the tip. No cervical glands were palpable. There was a soft precordial systolic murmur. A hard mass was palpable in the epigastrium, not tender, descending slightly with inspiration. The right lobe of the liver was not palpable.

The right ankle and knee jerks were not obtained.

Examination of the urine was negative. The blood showed a red cell count of 3,890,000, a

hemoglobin of 60 per cent, a white cell count of 9,000.

A gastro-intestinal x-ray series showed a slight irregularity of the duodenal cap on its upper border. No definite ulcer crater could be visualized.

Radium seeds were implanted in the carcinoma of the tongue. The following day x-ray therapy was started. She was discharged three days after admission and told to return to the Outpatient Department for further x-ray treatment.

History of interval Except for some smarting of her tongue during eating and increased irritability because of her headaches she was perfectly well following her discharge until three days before readmission. At that time, while waiting for x-ray treatment, she complained of a sick feeling in her stomach and suddenly vomited about a quart of watery food material mixed with blood. Her blood pressure was 140/85. At the previous admission it was 190/90.

Second admission, eight months after her previous discharge. She was kept in the Emergency Ward under observation. The following morning she suddenly vomited a quart or more of bright red blood and simultaneously had a bowel movement. The blood pressure dropped to 60/30 and the pulse rose to 140. She was placed on the shock table and given morphine and later a slow intravenous injection of two and a half per cent glucose. There was some improvement and her blood pressure rose to 108/35. Physical examination was practically the same as on her previous admission. The same smooth firm mass was felt in the upper epigastrium. Examination of her blood showed a red cell count of 3,050,000, a hemoglobin of 70 per cent, a white cell count of 10,800, with 90 per cent polymorphonuclears. The non-protein nitrogen of the blood was 62 milligrams, the blood sugar 139 milligrams, and the carbon dioxide combining power 48.2 volumes per cent.

She was given 600 cubic centimeters of citrated blood. The blood pressure rose to 120/140 systolic. She became comatose and had almost an acidotic breathing. She developed fluid in her chest and shortly before death had a generalized convulsion during which her face was drawn over to the right. She died the day following admission.

DR. TRACY B. MALLORY Dr. Winn, there is one thing that was not entirely clear from the record. Did she ever recover consciousness from the complete shock?

DR. W. A. WINN Not after the time of the second hemorrhage. She was irrational. The visiting physician brought up the question whether or not she had had too much morphine or whether the high non-protein nitrogen caused her coma.

DIFFERENTIAL DIAGNOSIS

DR ROBERT R LINTON In going over this case I have selected what I think are the essential points in the history First of all she was sixty-one years old At the time of her first admission she had cancer of the tongue, grade III, which was adequately taken care of, or presumably so, with radium and x-ray therapy It was noted at that time that she did not have any enlarged lymph nodes in her neck, so I presume she did not have any metastases

The next thing of interest in the past history is that she had a positive Wassermann and a positive Hinton So far as I can see this condition had not been treated

The story that she had no children is of interest, although I think it has nothing to do with the cause of death Her amenorrhea undoubtedly explains the fact that she did not have any children What the exact cause of that was I hesitate to say It may have been an endocrine condition and it may possibly have been a luetic or tuberculous condition

In addition she also had bilateral cataracts, one of these having been removed and the other being still present, but apparently it did not bother her enough for her to have anything done about it

On physical examination at the first entry she had a lesion on her tongue and in addition a perforated nasal septum Her right ankle and knee jerks were not obtained

Of significance I think was the mass that was felt in the midepigastrium, described as hard and smooth and moving on deep inspiration I think we should pay particular attention to that mass in trying to explain her death

Laboratory examination at that time showed that she had a secondary anemia.

X-ray examination showed a defect in the duodenal cap, but they could see no definite ulcer

She went home after she had had her radium and x-ray therapy and returned eight months later, presumably for further x-ray treatment Her history in this intervening time shows that she was fairly well She did have some headaches and I think had not felt quite up to par, although we are told here that she had felt perfectly well

The acute episode apparently started with the vomiting of a large amount of watery material which was food with blood mixed with it. That amount of bleeding of course would not point to any one lesion in particular except that there was some pathology in the gastro-intestinal tract There is no question that the blood was coughed up, it apparently was vomited The next morning she vomited a quart of bright red blood and with that she had a fall in blood pressure That I think is of considerably more significance than the fact that she had been vomiting food with a little blood in it

In spite of transfusion she rapidly went downhill Her blood studies and laboratory examinations were essentially negative except for the elevated non-protein nitrogen, which was taken in a period of shock and I think might possibly be explained by lowering of the blood pressure and shutting down of urinary excretion Following the transfusion she became comatose and died in a convulsion, the face drawing over to one side I should presume that was the terminal event and not the real cause of her death

To review the possibilities that this patient might have I think we shall agree that the cause of death was primary acute hemorrhage, and that it probably came from the gastro-intestinal tract

I forgot to mention that the mass in the midepigastrium on the second admission was exactly the same as at the previous entry I think that is of considerable importance She had carcinoma of the tongue It is possible but very improbable that she might have had metastatic carcinoma which was showing itself in the liver Against that also is the fact that the mass in the epigastrium had not changed Carcinoma of the tongue I think very rarely if ever metastasizes to the liver So I think we cannot explain her death on the basis that it might have been a metastatic lesion of cancer

Then there is the question whether or not she had a duodenal ulcer Her history is against that because she had no gastro-intestinal symptoms The x-ray suggested a duodenal ulcer, but this was not definite I think we can pretty definitely rule out duodenal ulcer as the cause of her acute hemorrhage

It is possible she had a cancer of the stomach with metastases to the liver and hemorrhage from the carcinoma in the stomach Against that, however, is the fact that the mass in the epigastrium had not changed in size

One of the most common causes of acute hemorrhage and massive hemorrhage such as this is esophageal varices associated with cirrhosis of the liver Physical examination noted that the mass could be felt in the left, but the right lobe could not be felt I do not think that means a small right lobe It may possibly have been a large lobe, for it may have been there but not have been palpated No note is made as to the size of the liver to percussion That might have given us a clue as to the size There is the question of the etiology of the cirrhosis, if she had it In the history it states that she took no drugs and no alcohol So presumably it was not an alcoholic cirrhosis She had a positive Wassermann and had it for a good many years without treatment I presume, and she had symptoms of tertiary lues and a positive blood It seems to me most likely that she died of acute hemorrhage from esophageal varices associated with

cirrhosis of the liver which I think may be luetic in origin

DR GRANTLEY W TAYLOR In regard to the etiology of her tongue condition, we have found that carcinoma of the tongue very frequently originates on a luetic basis. The Wassermann is positive in about twenty-five per cent of the cases of carcinoma of the tongue, which often perhaps brings about some delay in prompt treatment of cancer of the tongue, because a diagnosis of lues is made and at first it is assumed that the condition is a simple luetic glossitis without secondary carcinoma. The only other etiologic factor is possibly the false teeth, but those dentures are much more commonly associated etiologically with carcinoma of the palate or jaw than of the tongue.

In regard to the treatment of her tongue lesion, which appeared to be temporarily effective, we are getting more and more to depend on radiation almost to the exclusion of surgery in treatment of carcinoma of the tongue. If there are bad dental conditions or sepsis we try to clean them up and then combine interstitial radium treatment with x-ray treatment in doses which are very massive as compared with the treatment we used a few years ago.

The handling of the lymph node areas by operation seems to me much less common now than it was ten years ago. Cures of carcinoma of the tongue in which the cervical lymph nodes are involved are very rare and limited almost entirely to those cases which show only microscopic evidence of lymph node involvement. If there is evident gross involvement with metastatic disease the case is essentially incurable by any means. In regard to the possibility of remote metastasis from carcinoma of the tongue it does occur, but it is extremely rare. Dr Lund reviewed in the neighborhood of eleven hundred cases of carcinoma of the buccal mucosa in general at the Huntington Hospital and found no instances of metastasis beyond the clavicle. I recall one case with liver metastasis. When I was talking about it with Dr Hartwell he remembered one case, and it developed that they were the same case. I have seen one case with pulmonary involvement, but it must be extremely rare, and I think it would be unwise to assume that it had anything to do with this condition from which she died.

DR WILLIAM B BREED I am impressed with the ease with which Dr Linton ruled out hemorrhage from the duodenum on the basis of no digestive symptoms, because so many of these cases that bleed from the duodenum have had no digestive symptoms. I think these cases bleed more often than the ones that have had symptoms.

DR MALLORY There is one other point that deserves a little discussion, and that is the development and persistence of coma in this case.

It brings up the question as to whether or not there was a cerebral lesion.

DR W JASON MIXTER I think the question of coma is of considerable importance, and also the question of convulsions. In going over the records we find that the reflexes are present on one side and not on the other. It seems to me that an intracranial lesion must be suspected.

CLINICAL DIAGNOSES

Carcinoma of tongue, grade III
Late syphilis
Hematemesis
Cirrhosis of the liver?
Cerebral hemorrhage

ANATOMIC DIAGNOSES

Cirrhosis of the liver, toxic type
Esophageal varices
Duodenal erosion
Intestinal hemorrhage
Pulmonary edema
Pulmonary emphysema, slight
Operative wound—radiation scar for carcinoma of tongue
Operative wound—removal of cataract, right eye

PATHOLOGIC DISCUSSION

DR MALLOBY The autopsy here showed according to Dr Linton's prediction a very marked cirrhosis of the liver. There were esophageal varices, rather slight ones, we were unable to demonstrate a bleeding point. In addition I can side with Dr Breed, because there was a shallow ulcer in the duodenum. So from which of these two lesions she bled I do not know. At autopsy it seemed equally possible that either was the source of the hemorrhage.

The cirrhosis was a coarsely nodular one. The right lobe was very small and the left lobe distinctly a little big. The spleen was not enlarged, so the mass which had been felt was certainly the left lobe of the liver.

The brain I am going to ask Dr Kubik to tell you about. We have had two or three cases somewhat similar to this in patients who have had shock or hemorrhage. In each case there has been a tremendous drop in blood pressure which persisted for some time and definite cerebral symptoms developed, but we have not been able to find any occlusion of vessels or any hemorrhage. It raises the question whether the tremendously lowered blood pressure may result in cerebral degeneration. This patient had been carrying a pressure of 190, so that a drop to 60 would be more significant than in a non-hypertensive case. It seems possible that that is the cause of the cerebral lesion.

DR CHARLES S KUBIK Although there was no gross circumscribed lesion such as hemorrhage or infarct, there was found on microscopic

examination an interesting condition with a bilateral diffuse distribution in the cerebral cortex. Ganglion cells were damaged, glia cells (astrocytes) were swollen and increased in number and there was a decided increase in the amount of fibrous glia. The changes were much more pronounced in the fifth and sixth laminae, that is in the deep layers of the cortex. The glial changes are not restricted to the grey matter, but are also found in the outer zone of subcortical white matter. It is rather remarkable that there was little if any arteriosclerosis. The main arteries had thin translucent collapsed walls. There was probably some arteriosclerosis, but this did not seem to be marked.

The deep layers of the cortex seem to be particularly susceptible to degenerative changes. I recall two cases of delirium, one of which was probably a toxic affair resulting from the use of sedative drugs, in which similar changes were found. In another case, where death occurred two weeks after a severe degree of asphyxia, there was marked degeneration with complete destruction of myelin in this same region. The fact that this part of the cortex is particularly vulnerable when exposed to the effects of anoxemia or toxic agents is probably dependent in some way on the arrangement of its blood supply. In the case before us it is reasonable to suppose that the degenerative changes are due to a deficient supply of blood resulting from hemorrhage and exceedingly low blood pressure. The convulsion was probably a manifestation of relative anoxemia.

DR ALFRED KRANES: We have had several cases in the past two years in which after morphine the patients with cirrhosis became more and more comatose, almost like a myxedematous reaction to the drug. I wonder if any one else has seen it.

DR EDWARD B. BENEDICT: With regard to the hemorrhage, since the pathologists could not be sure of its source in this case, no one can tell, but Rivers and Wilbur of the Mayo Clinic recently reported that of all cases of gross hematemesis over 50 per cent are due to duodenal ulcer and only about 5 per cent are due to esophageal varices.

DR. MALLORY: It is the commonest cause, although this was a very shallow ulcer, not a particularly massive one.

CASE 20252

PRESENTATION OF CASE

A forty-eight year old unemployed Finn, formerly a dock laborer, entered complaining of weakness, abdominal pain and jaundice.

Approximately one year before admission he began to have mild indigestion and diarrhea. Over a period of one month he lost about ten pounds in weight. His family physician prescribed some drops to take at meal times. The

diarrhea cleared up, but he remained weak and continued to lose weight. About five months before entry he visited a large medical center in New York City where a diagnosis of pernicious anemia was made and liver therapy was begun. At about this time he developed a dragging sensation in his abdomen and a little later definite pain which radiated to the pubis. The pain was severe enough to keep him awake at night. He spent the summer before admission in Maine. His diet consisted for the most part of milk, lettuce, spinach and string beans. During the past three months he had vomited about once a month and during the past three weeks about once a week. The abdominal discomfort became worse. Three days before admission he developed a constant diarrhea consisting of three to five loose watery movements a day. He believed that he had been slightly jaundiced during these events and that he had lost in all approximately thirty-two pounds in weight. During the past month he had had slight edema of his right ankle.

The family and marital histories are non-contributory. The past history is negative.

Physical examination showed an emaciated, sunburned elderly man. The skin and mucous membranes were pale but not jaundiced. There was marked pyorrhea and caries of the teeth. There was a soft basal systolic murmur. The fundi showed moderate sclerosis. The blood pressure was 155/65. The pulse was 112 and Corrigan in character. The abdomen was protuberant and dull to percussion. This was interpreted as fluid. There was a hard irregular mass above and to the left of the umbilicus but below the epigastrium. There was a small strangulated hemorrhoid.

The temperature was 100°, the respirations 20.

Examination of the blood showed a red cell count of 3,200,000 with a hemoglobin of 45 per cent. The white cell count was 25,000, with 82 per cent polymorphonuclears. A smear showed the red cells to be normal. Examination of the stools was negative. A Hinton test was negative. A liver function test showed ten per cent retention. The icteric index was 8.

He failed very rapidly and died two days after admission. The terminal white cell count was 42,000.

DIFFERENTIAL DIAGNOSIS

DR DANIEL F. JONES: I always have admired Dr. Richard Cabot for the way he could make a diagnosis from these histories, and I admire him still more after seeing this history. He must have run across very similar cases in his long period of doing this work. I do not know that I have ever seen a history that has so little in it that is of any value. The patient comes in complaining of weakness, which is of importance, and which has been increasing for quite a period. He has abdominal pain, and the note

says that he has jaundice. The first question is whether he ever did have jaundice, and if possible the value of that statement by the patient should have been indicated in some way. It is evident that he did not have jaundice, or probably did not have jaundice, because he went to a clinic in New York where he was found to have "pernicious anemia." In addition to that a blood test was done here and the test for bile was found to be negative.

If we go on through the history we have some important points, but not very helpful in making a definite diagnosis. He has mild indigestion and diarrhea, which means something, but it could mean so many things that it does not mean much. The diarrhea cleared up. If it cleared up what we ought to know is whether or not he was then markedly constipated. That would help us in deciding as to whether he had something in the intestine, but merely to say he had diarrhea which cleared up is not of any value to the man who is reading the history.

He visited a large clinic in New York where a diagnosis of pernicious anemia was made. That would suggest that he did not have jaundice before he came in, but was *sallow*, the term that is used by laymen so much but does not mean jaundice in the great majority of cases.

We are in a hole in this case, so to speak. We have nothing to go on. When a patient has pain in the abdomen, that is of no value in making a diagnosis. If he has pain we must know what it is like, where it is, how severe it is, whether cramp-like, whether constant, and many other things, none of which are given us here, except the one thing a little later, a definite pain which radiated to the pubis. Abdominal pains radiating to the pubis are not very helpful. They sometimes suggest something in the bladder or pelvis, but that is all we can say about that. We get the severity of the pain later in that it kept him awake at times.

We have another point to help us out. One might not think it much, but with a history like this we have to jump at minor details. Here is a man who had milk, lettuce and string beans during the summer and nothing is said in regard to constipation or diarrhea during that time. That would suggest to my mind that he did not have any constriction of his bowel, because with such coarse food he certainly ought to have become much more constipated.

Three days before admission he developed constant diarrhea, three to five watery movements a day, and the patient believed he was jaundiced. The sudden development of loose watery movements without a pretty careful previous history would not suggest anything definite to me. It certainly ought not to suggest, after such a long period, a constricting growth in the bowel.

He has lost a tremendous amount of weight. Another thing which I would call to your

attention is that he has slight edema of the right ankle. I would call that to your attention because we have a mass in the left upper abdomen, but no other mass. That ought to suggest then a metastasis or something in the lower abdomen pressing on the right iliac vein rather than the left. We have the mass in the left side, therefore that should have nothing to do with the edema of the ankle.

When we come to the physical examination, what can we get out of that? He is a sunburned man, pale, but not jaundiced. So it is probable that he never has been jaundiced with our other evidence. There is marked pyorrhea and caries of the teeth, which amounts to very little. The abdomen was protuberant and dull to percussion. I agree entirely with what Dr. Vincent said in regard to fluid in the abdomen, that it is a very difficult condition to determine accurately. I have seen all sorts of men make all sorts of errors in regard to it. But his abdomen was protuberant and was dull to percussion. We must pay some attention to that, probably fluid.

There is a hard irregular mass just above the umbilicus but below the epigastrium. That is pretty slight evidence. It moved slightly with respiration. We do not know whether it moved by manual pressure. So that this mass is rather an indefinite thing. We do not know whether it is retroperitoneal, whether it is in the transverse colon, whether it is in the omentum, or whether it is deep in the region of the pancreas, although of course if it is pancreas it would be at the lower border of the pancreas and not at the usual site for growth in the pancreas.

His temperature was 100°, which is of very little value in making a diagnosis. When there is a mass in the abdomen you could get an increased temperature and do get it very frequently in malignant disease, and it does not necessarily mean an inflammatory process.

The hemoglobin was 45, the white cell count 25,000. 25,000 is rather high, but still we could say that it was due to malignant disease.

Examination of the stools was negative. For what was it negative? Was it negative for blood? We do not know.

He had a negative Hinton test. The liver function showed 10 per cent retention. The icteric index was 8. He failed rapidly and died two days after admission.

In a case as blind as this a very careful, thorough examination of the abdomen is of importance. I do not see how one can possibly make a diagnosis without one.

The next thing is that we know there is a mass in the abdomen, with the suggestion of fluid, and great loss of weight, so we have a right to assume that this is malignant disease. This is, then, malignant disease, and we have some evidence that there is something on the right side of the pelvis to cause edema of the

right ankle. There ought to be something in the pelvis to be made out in some way and we have no rectal examination. That according to my thoughts would be of the greatest importance. So that we are trying to make a diagnosis on what I should call a very small history with very little in the way of physical examination. We have a mass in the left upper quadrant not well up in the quadrant but beyond the umbilicus. If it were in the transverse colon it should be somewhat movable and we ought to find something such as blood to suggest that it is in the transverse colon. If it is in the omentum then we should find something that would suggest that it is in the omentum, as proximity to the anterior abdominal wall, or its arc of rotation. We have none of these things to help us.

There is one other point that we must consider, that is, his great loss of weight and diarrhea. We might consider in such a case as that with a mass in the position of this mass a carcinoma or a growth of some kind in the pancreas that would account for the location of the mass, for the diarrhea, for the great weakness and for his color, but it would hardly account for the 45 per cent hemoglobin. I do not know how to account for that with a negative examination of the stool. A man with 3,200,000 red cells and 45 per cent hemoglobin ought to have had bleeding from somewhere, ought to have had a long continued hemorrhage. We must not forget that in growths in the colon from the cecum to the splenic flexure one symptom they have of importance is anemia, that many cases of carcinoma of the cecum have nothing but anemia and no pain. We have no pain suggesting large intestine pain, that is, pain below the umbilicus, except this pain which radiates to the symphysis, which means very little to my mind, and does not suggest pain due to the large intestine. So we have no pain suggesting the large intestine unless the man was so far along with his obstruction that the pain was localized near the growth. Then a patient forgets entirely that he has lower abdominal pain and says it is located in the region of the growth, and this man was far advanced.

I shall have to make a diagnosis in this case on general principles, that is, a man who had lost a great deal of weight, was anemic, had a mass in the left upper quadrant a little above the umbilicus, pain radiating to the symphysis, and abdominal pain, whatever that means. Abdominal pain would mean to me nothing in particular. I could not get anything definite out of it. If I only knew what was in the pelvis I

should feel very much more certain about the diagnosis. However, we do not know what was in the pelvis, therefore we must go on general principles, loss of weight, loss of strength, a mass just above the umbilicus, indefinite abdominal pain, fluid, all suggesting to my mind a general carcinomatosis of the abdomen rather than a growth in the pancreas or a growth in the large intestine. I feel that we should have some cause for the 45 per cent hemoglobin, which suggests hemorrhage to my mind.

CLINICAL DIAGNOSIS

Abdominal malignancy

ANATOMIC DIAGNOSIS

Carcinoma of the stomach with perforation into the transverse colon

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY. I should like to assure Dr. Jones that we did not leave out anything. We gave him the entire history as it stands in the record and would gladly give him more if we could.

The point that interested me in this man's story was the fact that he had a flat-footed diagnosis of pernicious anemia made about a year and a half before at a leading hospital in New York, presumably on adequate grounds, and then he later developed the picture of malignancy. How much one would be justified in concluding from that I do not know, but it is certainly a fact that carcinomas of the stomach are not infrequently associated with a pernicious anemia blood picture which might lead one to place the malignancy there even though the physical examination did not particularly suggest it.

Our autopsy was limited to a six-inch incision in the abdomen, which the surgeons would probably consider very adequate, but which hampered us slightly, and I do not think we made as careful an exploration of the pelvis as Dr. Jones would have liked us to make. We did find a large tumor mass in the upper abdomen which involved both the stomach and the transverse colon, and a definite fistula between the two. So I think there is very little question but that it is primary carcinoma of the stomach ulcerating through to the transverse colon in the very last few days of life and would probably account for the sudden terminal development of diarrhea. The negative stools made it impossible to make that diagnosis ante mortem.

SOME FEATURES OF THE A M A CLEVELAND MEETING

A LARGE and enthusiastic meeting of the
American Medical Association convened at
Cleveland for the week beginning Monday,
June 11, 1934

The section meetings were of great excellence,
and well attended. The scientific exhibits pre-
sented the latest advances in dealing with dis-
ease, public health problems, and social features
of medicine. These exceeded the variety and
scope of previous years, and one might spend
the entire week to advantage in study of the in-
struction provided in this department.

As a form of medical education, if the grad-
uating classes of medical schools could have been
brought to Cleveland this year and conducted
through the spacious hall in which this scientific
display was presented, the average student would
probably supplement his four years of study
with more exact and useful information than
he has acquired hitherto.

In several instances motion pictures set forth
the facts in an impressive manner.

The *Cleveland Plain Dealer* in reporting the
session of the House of Delegates referred to
health insurance and veterans' hospitalization
as "hot poker" introduced into the delibera-
tions of this legislative body of the Association.
The reaction to the hospitalization of veterans
was a repetition of previous expressions. The
references to health insurance were in response
to a resolution by the Michigan State Medical
Society asking for the appointment of a com-
mittee to consider the A M A policy toward
mutual health service, and also the report of the
medical service Board of the American College of
Surgeons to the Board of Regents in which are
set forth the recommendations of this Board as
shown in a copy furnished by Dr. Franklin H.
Martin which appears on page 1345 of this issue.

This report was accepted and approved by the
Board of Regents of the American College of
Surgeons, and shows that this body, as repre-
sented by its Regents, believes in health insur-
ance for the low income group, with the elimina-
tion of certain objectionable features of the
customs abroad. This document also suggests
minimum standards for industrial medicine and
traumatic surgery.

It is of interest to note that Dr. Robert B.
Greenough is chairman of the Medical Service
Board of the American College of Surgeons.
When the attention of the House of Delegates
was called to the Michigan request and the ac-
tion of the College of Surgeons, Dr. Charles L.
Whalen of Chicago voiced his disapproval of the
attitude of these organizations, and a recess com-
mittee was appointed to consider the request of
the Michigan State Society. This probably
means that no action will be taken on this re-
port until the House of Delegates meets again,
and is an indication of a desire to postpone ac-
tion although this subject has been under discus-
sion for more than a year.

When this appeal of the Michigan Society
came before the House of Delegates, the House
went into executive session, but the newspaper
reports of the proceedings indicated disapproval
of any action by organizations of constituent
members of the American Medical Association.

In defining its position the House of De-
legates adopted a ten-point declaration of policy
contained in a report of a committee headed by
Dr. Nathan B. Van Etten of New York which
is as follows:

1—All features of medical service in any
method of medical practice should be under
the control of the medical profession. No other
body or individual is legally or educationally
equipped to exercise such control.

2—No third party must be permitted to come
between the patient and his physician in any
medical relation. All responsibility for the

character of medical service must be borne by the profession

3—Patients must have absolute freedom to choose a legally qualified doctor of medicine who will serve them from among all those qualified to practice and who are willing to give services

4—The method of giving the service must retain a permanent, confidential relation between the patient and a "family physician" This relation must be the fundamental and dominating feature of any system

5—All medical phases of all institutions involved in the medical service should be under professional control, it being understood that hospital service and medical service should be considered separately These institutions are but expansions of the equipment of the physician He is the only one whom the laws of all nations recognize as competent to use them in the delivery of service The medical profession alone can determine the adequacy and character of such institutions Their value depends on their operation according to medical standards

6—However the cost of medical service may be distributed, the immediate cost should be borne by the patient able to pay at the time the service is rendered

7—Medical service must have no connection with any cash benefits

8—Any form of medical service should include within its scope all qualified physicians of the locality covered by its operation who wish to give service under the conditions established

9—Systems for the relief of low income classes should be limited strictly to those below the "comfort level" standard of incomes

10—There should be no restrictions on treatment or prescribing not formulated and enforced by the organized medical profession

Much of this is quite like the plan adopted by the Michigan State Society, and also in conformity with several features of the report accepted by the Board of Regents of the American College of Surgeons, and it seems unusual for an organization like the American Medical Association to be disturbed because other organizations whose members are also members of the larger organization are studying existing conditions and codifying conclusions

The feeling expressed by the President of the New Jersey Society at the last annual meeting of that society to the effect that the American Medical Association has been disinclined to formulate policies, has been endorsed in some quarters, and justifies independent study and action even by members of the A. M. A. Although the great power and creditable accomplishments of the A. M. A. are recognized, the attitude of criticism of honest attempts to clarify some of the great problems before the country has not been conducive to harmony

The general spirit of the Cleveland meeting

as shown in the devotion to the service of humanity was a reflection of the ambition of the profession to advance medicine to still further knowledge of the problems before it This convention was one of the best in the history of organized medicine

The President-Elect is James Somerville McLester who was born in 1877 and graduated from the University of Virginia, Department of Medicine in 1899 He is Professor of Medicine in the University of Alabama School of Medicine with an office at 930 South 20th Street, Birmingham, Alabama

Massachusetts was recognized in the election of Dr. Roger I. Lee to the position of Trustee Dr. Emmett C. North of Missouri was elected a member of the Judicial Council

The next annual meeting will be at Atlantic City

QUINTUPLETS

DESPITE the bursts of public enthusiasm and inspirational journalism which have attended the most extraordinary instance so far recorded of what might euphemistically be termed synchronous multiparity, the birth of quintuplets is nevertheless of distinct medical interest In all medical history something over thirty cases of quintuplets have been recorded, no properly authenticated case of sextuplets Prior to the notable achievement of Olivia Dionne, no unquestionable set of quintuplets has survived as such for more than fifty minutes At the time of writing the Canadian quintuplets, weighing a total of thirteen pounds at birth, have traveled in each other's company, their ranks unbroken, through this vale of tears for fifteen days Perhaps they are aware of their goal and are striving for its attainment—exhibitionism on a family pedestal in the World's Fair at Chicago

According to Professor Alan F. Guttmacher of Johns Hopkins University, multiple births are most likely to occur between the ages of thirty-five and forty The mother of our present quintuplets is an exception to the rule, boasting only twenty-four summers, seven less than her husband The rarity of birth multiplicity increases, obviously, with the number of babes at the birth W. W. Greulich of the University of Colorado studied 100,000,000 births, establishing one in 87 as the chance for twin births The square of 87, or 7,569 gives the chances in favor of triplets, its cube, or 658,503 the chances in favor of quadruplets If this rule continues to hold true in the higher registers, quintuplets should make their appearance once in every 57,289,761 births!

The chances of all five surviving the period of infant mortality, at this rate, would require an array of digits so far known only to astronomy

MISCELLANY

BOSTON MEDICAL LIBRARY

The settling of an estate has provided an exceptional opportunity for the procuring of a lot of twenty-one manuscripts and incunabula for the Bulard and Hyams Collections

Two notable and exceedingly important manuscripts are included in the lot the "De proprietatibus rerum" of Bartholomaeus Anglicus and the Organon or Logica of Aristoteles Both of these books were common textbooks in the Middle Ages, and essential for all scholars

The manuscript of Bartholomaeus is a very large work of 298 leaves of vellum and probably was written in the North of Spain in the last part of the thirteenth century It is said to be from the Abbey of Leyre in Spanish Navarre and is in the original binding of deerskin over wooden boards with primitive iron bosses The end leaves used in the binding are parts of a vellum manuscript of the decretals of Gregory X. The text is a good one and well written

Bartholomaeus Anglicus was a Franciscan who was born in England and who flourished in the thirteenth century from about 1220 to at least 1250 A.D. His encyclopedia, which was written about 1230 to 1240, was for the plain people and was entitled "The properties of things" It was written in Latin and

based on the Bible, and while its aim was primarily theological and philosophical, it had much of natural history in its contents. It was comprehensive and methodical.

The work is divided into nineteen books which may be roughly designated as follows: 1. God, 2. angels and demons, 3. psychology, 4-5. physiology, 6. family life, 7. medicine, 8. cosmology and astrology, 9. time divisions, 10. form and matter and elements, 11. air and meteorology, 12. flying creatures, 13. waters and fishes, dolphins and whales, 14. physical geography, 15. political geography, 16. gems, minerals and metals, 17. trees and herbs, 18. animals, 19. color, odor, savor, food and drink, eggs, weights and measures, musical instruments. According to Sarton, the medical chapter is largely derived from Constantinus Africanus and the Herbal by far the most notable work of its kind written by an Englishman in the Middle Ages.

The work was very popular and was translated in the manuscript period into Italian, French, English, Spanish and all of these translations were published in incunabula editions. Fifteen editions were printed in Latin alone during the fifteenth century and it continued to be printed until the early part of the seventeenth century. It was one of the books made available to Paris students for a definite period.

Aristotelian logic was a primary subject in the curriculum of the schools and universities of the Middle Ages. The manuscript in the Library contains the usual course in logic, part of which is in the version of Boethius. It is written in good cursive hand on 111 leaves of vellum and is probably an Italian fourteenth century work. There are numerous interlinear and marginal notes in several hands, contemporary with the manuscript and later. It contains many erasures and corrections of the text, mostly in a hand not much later than that of the manuscript.

The initials are in red and green, with edges prolonged to form borders, and some have primitive grotesque ornaments like Italian work of the fourteenth century.

The text closely approximates that of the first printed edition of the *Organon* (Naples, 1473-78).

The *"Libro delle consolazione delle medicine"* of Joannes Mesne Junior, printed at Modena, 1475, is a very important and very rare incunabulum. It is the first edition of the Italian translation of the celebrated and popular work of Iesue and the first large medical book in the Italian language. The *Grabadin* or apothecary's manual of the pseudo-Mesue was very popular in the Middle Ages. The Latin printing of 1471 shares with the two Jenson tracts of the same year the honor of being the first dated medical books.

Volume one of the *"Rosarium sermonum"* of Bernardino de Bustis, Venice, 1498, contains an important sermon on the pest entitled *"De pestilente signis causis et remediis"*. In this sermon many medical authorities are quoted among which

may be mentioned, Hippocrates, Galen, Haly Abbas, Averroes, Albertus Magnus, Petrus de Abano, Aristoteles and Avicenna. Mention also is made of the great plague at Milan in 1451.

The *"Sermones quadragesimales"* of Robertus Caracciolus, Venice, 1479, contains an elaborate discussion of circumcision and a long sermon on pestilence in which the author is less concerned with the disease itself than with the sins for which he regards it as a chastisement. The sermon on women is curious, to say the least, and he gravely discusses whether women were produced with the other animals or made from man or made directly by the Divine Creator.

Other interesting works in the lot are the *"Mariale"* of Albertus Magnus (Basel, 1475), in which the miraculous conception of the Virgin is discussed in nine chapters and really has to do with generation, and the *"Homiliae"* of Gregory the Great, Venice, 1493, containing the famous homily against the astrologers. The collection of tracts of Petrus de Abano, Arnoldus de Villa Nova and Valascus de Taranta, on poisons and the pest, Padua, 1487, is an important medical work.

Strabo's *"Geographia"*, Venice, 1494, Dionysius Periegetes, *"Cosmographia"*, Venice, 1498, and Petrus de Cruce, *"Questio de ratione subjecti primi scientiae"*, Venice, 1500, are important scientific books.

The *"Cato moralisatus"* with the commentary of Philippus de Pergamo, commonly known as the *"Speculum regiminis"*, Lyon, 1497 and 1498, is a rare edition and contains much of medical interest. The commentator lived at Padua where there was a great medical school and he had much to say about medicine, and more about doctors, much of it is complimentary.

Two classical texts are the *"Facta et dicta memorabilia"* of Valerius Maximus, Venice, 1474 and the commentary of Dionysius de Burgo, on the same work, printed by the R printer of Strassburg about 1471. The last is very interesting from a typographical point of view. Dionysius devotes considerable space to a legend of Aesculapius and twenty-eight pages to dreams. He also discusses at length the question of death, both real and apparent.

REPORT OF THE MEDICAL SERVICE BOARD OF THE AMERICAN COLLEGE OF SURGEONS, JUNE 10, 1934

The Medical Service Board of the American College of Surgeons respectfully submits the following report to the Board of Regents:

1. The American College of Surgeons affirms its interest and its desire to cooperate with other agencies looking toward the provision of more adequate medical service to the whole community.

2. The College believes that it is the duty of the medical profession to assume leadership in this movement and to take control of all measures directed to this end.

- a The Minimum Standard for Industrial Medicine and Traumatic Surgery of the American College of Surgeons should be accepted. This standard is as follows

MINIMUM STANDARD FOR INDUSTRIAL MEDICINE
AND TRAUMATIC SURGERY

1 That the industry shall have an organized medical department, or service with competent medical staff including consultants and adequate emergency dispensary and hospital facilities and personnel to assure efficient care of the ill and injured

2 That membership on the medical staff shall be restricted to physicians and surgeons who are (a) graduates of scientific medicine holding the degree of Doctor of Medicine in good standing and licensed to practice in their respective states or provinces (b) competent in the field of industrial medicine and traumatic surgery (c) worthy in character and in matters of professional ethics that in the latter connection the practice of the division of fees under any guise whatsoever be prohibited

3 That there shall be a system of accurate and complete records filed in an accessible manner—a complete record being one which includes identification data cause of illness or injury nature and extent of illness or injury detailed description of physical findings special examinations such as consultations clinical laboratory and x-ray tentative or provisional diagnosis treatment prognosis with estimated period of disability progress of illness or injury final diagnosis condition on discharge end results and such additional information as may be required by statute for Workmen's Compensation claims or for other purposes

4 That all patients requiring hospitalization shall be sent to institutions approved by the American College of Surgeons

5 That the medical department shall have general supervision over the sanitation of the plant and the health of all employees

b Physicians and surgeons qualified as in paragraph 2 of the above minimum standard may properly be employed on a full time or a part time basis by industrial organizations to provide medical and surgical service for their employees as follows

i To provide emergency service and first aid in injury or disease and to provide adequate medical or surgical care for industrial injuries and diseases Medical and surgical care of the families of employees and of employees themselves except for emergency and industrial injuries and diseases should be provided by the industrial physician only in remote districts where other adequate medical service is not available

ii To provide pre-employment and periodic physical examinations

iii To study the hazards of the particular industry and to cooperate with other agencies in effecting such measures as may be needed for the prevention of injury and disease

iv To keep accurate records such as may be required by local Workmen's Compensation laws, and so complete as to serve for scientific investigation of industrial hazards with a view to their further prevention These records are privileged communications, subject always to due process of law

c The sale of a contract by an industrial organization to an individual physician or group of physicians for medical and/or hospital service for its employees encourages commercial competition and is to be condemned

d Unethical practices in publicity, advertising solicitation, and competition either of a professional or of a financial nature, must be eliminated

e The accepted code of ethics of the medical profession which is designed to protect the best interests of the patient should apply to industrial medical service as to all other forms of medical practice

THE CONDITIONS AT THE
BROOKLINE TUBERCULOSIS HOSPITAL

About May 1 a patient at the Brookline Tuberculosis Hospital sent a letter to the Board of Health complaining of the food at the Hospital. The complaint was referred to Dr. Francis P. Denny, the Health Officer and Medical Director of the Hospital for investigation. Dr. Denny reported that as a result of his investigation he was satisfied that the food was good. A second letter from the same patient was received on May 21, and on adjournment four members visited the Hospital without warning to the staff just at the time of the evening meal. Opportunity was given to all the patients to say what they thought of the food. After their visit the members of the Board expressed their satisfaction with the conditions which they found at the Hospital.

The day following the patient who had made the complaint left the Hospital and stated to the press that he would not return until the cook at the Hospital had been discharged. He drew up a petition to the Board which was signed by eleven other patients requesting that the cook be discharged.

At its meeting on June 4, after a conference with the Superintendent, Miss Elizabeth McMahon and Dr. Denny, the Board voted unanimously to take no action on the petition.

3 Encouragement should be given to the trial of new methods of practice designed to meet these needs and a careful evaluation of their success should be the duty of the medical profession before they are offered for general adoption. All such new and experimental methods of practice must be conducted strictly in accordance with the accepted code of ethics of the medical profession in order that the interests of the patient and of the community may be protected.

4 The College recognizes for immediate study four groups of the population for whom more adequate medical service should be made available as follows:

- a The indigent.
- b The uneducated and credulous members of the community.
- c Those who because of limited resources are unable unaided to meet the costs of serious illness and hospitalization.
- d Those living in remote districts where adequate medical service is not obtainable.

5 The care of the indigent sick should be a direct obligation upon the community and (unless otherwise compensated by intangible benefits such as staff and teaching appointments, opportunity and experience) physicians fulfilling this public service should receive remuneration.

6 The College should work in cooperation with other medical groups in order to dispel the ignorance and credulity of the public and to bring the people to a proper realization of the protective and curative resources of modern medicine.

7 The American College of Surgeons recognizes that the periodic pre-payment plan providing for the costs of medical care of illness and injury of individuals and of families of moderate means offers a reasonable expectation of providing them with more effective methods of securing adequate medical service.

A number of different plans for the organization of such services have been proposed although few have been in operation long enough to permit definite conclusions in regard to their success. It is to be desired that these experiments be continued. Conditions differ to such a degree in different parts of the country that a specific plan which is practicable in one place may require modification of details in other communities. The varying restrictions imposed by present insurance laws in different states further complicate the problem.

Periodic pre-payment plans providing for the costs of medical service may be divided into two classes:

- A Payment for medical service
- B Payment for hospitalization

It is suggested that plans for the payment of hospitalization alone (Class B) without provision for payment for medical service, may be considered the first project to be undertaken in the average community.

The American College of Surgeons believes that certain general principles can and should be established, the observance of which will tend to obviate known difficulties and dangers which may threaten the success of these special forms of medical service. These principles are as follows:

- a Periodic pre-payment plans for medical service should be free from the intervention of commercial intermediary organizations operating for profit. After deduction of the clerical costs of operation of the fund and such accumulation of reserve as may be advisable in the interest of the contributors or may be legally imposed, the full amount paid by the contributors should be available for medical and hospital services.
- b In the interest of the patient the organization of plans for the periodic payment of medical and hospital costs must be under the control of the medical profession. The medical profession must act in concert with the hospitals and such other allied services as may be involved in the individual project together with a group of citizens representative of the whole community and of industry who are interested in the successful operation of the plan.
- c The principle of free choice of the physician and hospital by the patient must be assured to the end that the responsibility of the individual physician to the individual patient shall always be maintained. When hospitalization is required, this choice must of necessity be limited to the physicians and surgeons who hold appointments on the staffs of the hospitals participating in the plan or to those physicians and surgeons who are acceptable to the hospital. It is further recommended that only approved hospitals be admitted to participation in such a plan.
- d The compensation of the physician and of the hospital should be estimated with due regard to the resources available in the periodic payment fund and should be based upon the specific services rendered.
- e The organization and operation of any plan of this type must be free from any features not in accordance with the code of ethics of the medical profession which code has been established for the protection of the patient.
- f The medical organizations participating in such a plan must assume the responsibility for the quality of service rendered.

8 Periodic pre-payment plans for medical and hospital service should eliminate many of the conditions which have brought about the development of industrial contract practice. Until such plans have been more widely established, certain general principles are here formulated with a view to the elimination of the commercial features of such forms of medical service.

- a The Minimum Standard for Industrial Medicine and Traumatic Surgery of the American College of Surgeons should be accepted. This standard is as follows:

MINIMUM STANDARD FOR INDUSTRIAL MEDICINE
AND TRAUMATIC SURGERY

- 1 That the industry shall have an organized medical department, or service with competent medical staff including consultants and adequate emergency dispensary and hospital facilities and personnel to assure efficient care of the ill and injured.
- 2 That membership on the medical staff shall be restricted to physicians and surgeons who are (a) graduates of scientific medicine holding the degree of Doctor of Medicine in good standing and licensed to practice in their respective states or provinces; (b) competent in the field of industrial medicine and traumatic surgery; (c) worthy in character and in matters of professional ethics that in the latter connection, the practice of the division of fees under any guise whatsoever be prohibited.
- 3 That there shall be a system of accurate and complete records filed in an accessible manner—a complete record being one which includes identification data, cause of illness or injury, nature and extent of illness or injury, detailed description of physical findings, special examinations such as consultations, clinical laboratory and x-ray, tentative or provisional diagnosis, treatment, prognosis with estimated period of disability, progress of illness or injury, final diagnosis, condition on discharge, end results and such additional information as may be required by statute for Workmen's Compensation claims or for other purposes.
- 4 That all patients requiring hospitalization shall be sent to institutions approved by the American College of Surgeons.
- 5 That the medical department shall have general supervision over the sanitation of the plant and the health of all employees.
- b Physicians and surgeons qualified as in paragraph 2 of the above minimum standard may properly be employed on a full time or a part time basis by industrial organizations to provide medical and surgical service for their employees as follows:
 - i To provide emergency service and first aid in injury or disease and to provide adequate medical or surgical care for industrial injuries and diseases. Medical and surgical care of the families of employees and of employees themselves except for emergency and industrial injuries and diseases should be provided by the industrial physician only in remote districts where other adequate medical service is not available.

- B Payment for hospitalization

It is suggested that plans for the payment of hospitalization alone (Class B) without provision for payment for medical service may be considered the first project to be undertaken in the average community.

The American College of Surgeons believes that certain general principles can and should be established, the observance of which will tend to obviate known difficulties and dangers which may threaten the success of these special forms of medical service. These principles are as follows:

- a. Periodic pre-payment plans for medical service should be free from the intervention of commercial intermediary organizations operating for profit. After deduction of the clerical costs of operation of the fund and such accumulation of reserve as may be advisable in the interest of the contributors or may be legally imposed the full amount paid by the contributors should be available for medical and hospital services.
- b. In the interest of the patient, the organization of plans for the periodic payment of medical and hospital costs must be under the control of the medical profession. The medical profession must act in concert with the hospitals and such other allied services as may be involved in the individual project, together with a group of citizens representative of the whole community and of industry who are interested in the successful operation of the plan.
- c. The principle of free choice of the physician and hospital by the patient must be assured to the end that the responsibility of the individual physician to the individual patient shall always be maintained. When hospitalization is required, this choice must of necessity be limited to the physicians and surgeons who hold appointments on the staffs of the hospitals participating in the plan or to those physicians and surgeons who are acceptable to the hospital. It is further recommended that only approved hospitals be admitted to participation in such a plan.
- d. The compensation of the physician and of the hospital should be estimated with due regard to the resources available in the periodic payment fund and should be based upon the specific services rendered.
- e. The organization and operation of any plan of this type must be free from any features not in accordance with the code of ethics of the medical profession which code has been established for the protection of the patient.
- f. The medical organizations participating in such a plan must assume the responsibility for the quality of service rendered.

8 Periodic pre-payment plans for medical and hospital service should eliminate many of the conditions which have brought about the development of industrial contract practice. Until such plans have been more widely established certain general principles are here formulated with a view to the elimination of the commercial features of such forms of medical service.

- a The Minimum Standard for Industrial Medicine and Traumatic Surgery of the American College of Surgeons should be accepted. This standard is as follows

MINIMUM STANDARD FOR INDUSTRIAL MEDICINE
AND TRAUMATIC SURGERY

- 1 That the industry shall have an organized medical department or service with competent medical staff including consultants and adequate emergency dispensary and hospital facilities and personnel to assure efficient care of the ill and injured
- 2 That membership on the medical staff shall be restricted to physicians and surgeons who are (a) graduates of scientific medicine holding the degree of Doctor of Medicine in good standing and licensed to practice in their respective states or provinces (b) competent in the field of industrial medicine and traumatic surgery (c) worthy in character and in matters of professional ethics that in the latter connection the practice of the division of fees under any guise whatsoever be prohibited
- 3 That there shall be a system of accurate and complete records filed in an accessible manner—a complete record being one which includes identification data cause of illness or injury nature and extent of illness or injury detailed description of physical findings special examinations such as consultations clinical laboratory and x-ray tentative or provisional diagnosis treatment prognosis with estimated period of disability progress of illness or injury final diagnosis condition on discharge end results and such additional information as may be required by statute for Workmen's Compensation claims or for other purposes
- 4 That all patients requiring hospitalization shall be sent to institutions approved by the American College of Surgeons
- 5 That the medical department shall have general supervision over the sanitation of the plant and the health of all employees
- b Physicians and surgeons qualified as in paragraph 2 of the above minimum standard may properly be employed on a fulltime or a part time basis by industrial organizations to provide medical and surgical service for their employees as follows
 - i To provide emergency service and first aid in injury or disease and to provide adequate medical or surgical care for industrial injuries and diseases Medical and surgical care of the families of employees and of employees themselves except for emergency and industrial injuries and diseases should be provided by the industrial physician only in remote districts where other adequate medical service is not available
 - ii To provide pre-employment and periodic physical examinations
 - iii To study the hazards of the particular industry and to cooperate with other agencies in effecting such measures as may be needed for the prevention of injury and disease

- c The care of the organization to be organized of physicians to be service for the commercial companies
- d Unethical practices of solicitation, and professional or of a fee eliminated.
- e The accepted code of profession which is the interests of the industrial medical service of medical practice

THE CONDITIONS AT THE
BROOKLINE TUBERCULOSIS HOSPITAL

About May 1 a patient at the Brookline Tuberculosis Hospital sent a letter to the Board of Health complaining of the food at the Hospital. The complaint was referred to Dr. Francis P. Denny, Jr., Health Officer and Medical Director of the Hospital for investigation. Dr. Denny reported that as a result of his investigation he was satisfied that the food was good. A second letter from the same patient was received on May 21, and on adjournment four members visited the Hospital without warning to the staff just at the time of the evening meal. Opportunity was given to all the patients to say what they thought of the food. After their visit the members of the Board expressed their satisfaction with the conditions which they found at the Hospital.

The day following the patient who had made the complaint left the Hospital and stated to the press that he would not return until the cook at the Hospital had been discharged. He drew up a petition to the Board which was signed by eleven other patients requesting that the cook be discharged.

At its meeting on June 4 after a conference with the Superintendent Miss Elizabeth McMahon and Dr. Denny the Board voted unanimously to take no action on the petition.

3 Encouragement should be given to the trial of new methods of practice designed to meet these needs, and a careful evaluation of their success should be the duty of the medical profession before they are offered for general adoption. All such new and experimental methods of practice must be conducted strictly in accordance with the accepted code of ethics of the medical profession in order that the interests of the patient and of the community may be protected.

4 The College recognizes for immediate study four groups of the population for whom more adequate medical service should be made available, as follows:

- a The indigent.
- b The uneducated and credulous members of the community.
- c Those who because of limited resources are unable, unaided, to meet the costs of serious illness and hospitalization.
- d Those living in remote districts where adequate medical service is not obtainable.

5 The care of the indigent sick should be a direct obligation upon the community and (unless otherwise compensated by intangible benefits such as staff and teaching appointments, opportunity and experience) physicians fulfilling this public service should receive remuneration.

6 The College should work in cooperation with other medical groups in order to dispel the ignorance and credulity of the public, and to bring the people to a proper realization of the protective and curative resources of modern medicine.

7 The American College of Surgeons recognizes that the periodic pre-payment plan providing for the costs of medical care of illness and injury of individuals and of families of moderate means offers a reasonable expectation of providing them with more effective methods of securing adequate medical service.

A number of different plans for the organization of such services have been proposed, although few have been in operation long enough to permit definite conclusions in regard to their success. It is to be desired that these experiments be continued. Conditions differ to such a degree in different parts of the country that a specific plan which is practicable in one place may require modification of details in other communities. The varying restrictions imposed by present insurance laws in different states further complicate the problem.

Periodic pre-payment plans providing for the costs of medical service may be divided into two classes:

- A Payment for medical service
- B Payment for hospitalization

It is suggested that plans for the payment of hospitalization alone (Class B) without provision for payment for medical service, may be considered the first project to be undertaken in the average community.

The American College of Surgeons believes that certain general principles can and should be established, the observance of which will tend to obviate known difficulties and dangers which may threaten the success of these special forms of medical service. These principles are as follows:

- a. Periodic pre-payment plans for medical service should be free from the intervention of commercial intermediary organizations operating for profit. After deduction of the clerical costs of operation of the fund and such accumulation of reserve as may be advisable in the interest of the contributors or may be legally imposed, the full amount paid by the contributors should be available for medical and hospital services.
- b. In the interest of the patient, the organization of plans for the periodic payment of medical and hospital costs must be under the control of the medical profession. The medical profession must act in concert with the hospitals and such other allied services as may be involved in the individual project, together with a group of citizens representative of the whole community and of industry who are interested in the successful operation of the plan.
- c. The principle of free choice of the physician and hospital by the patient must be assured to the end that the responsibility of the individual physician to the individual patient shall always be maintained. When hospitalization is required, this choice must of necessity be limited to the physicians and surgeons who hold appointments on the staffs of the hospitals participating in the plan or to those physicians and surgeons who are acceptable to the hospital. It is further recommended that only approved hospitals be admitted to participation in such a plan.
- d. The compensation of the physician and of the hospital should be estimated with due regard to the resources available in the periodic payment fund and should be based upon the specific services rendered.
- e. The organization and operation of any plan of this type must be free from any features not in accordance with the code of ethics of the medical profession which code has been established for the protection of the patient.
- f. The medical organizations participating in such a plan must assume the responsibility for the quality of service rendered.

8 Periodic pre-payment plans for medical and hospital service should eliminate many of the conditions which have brought about the development of industrial contract practice. Until such plans have been more widely established, certain general principles are here formulated with a view to the elimination of the commercial features of such forms of medical service.

- 1 That the industry shall have an organized medical department or service with competent medical staff including consultants and adequate emergency dispensary and hospital facilities and personnel to assure efficient care of the ill and injured
- 2 That membership on the medical staff shall be restricted to physicians and surgeons who are (a) graduates of scientific medicine holding the degree of Doctor of Medicine in good standing and licensed to practice in their respective states or provinces (b) competent in the field of industrial medicine and traumatic surgery (c) worthy in character and in matters of professional ethics that in the latter connection the practice of the division of fees under any guise whatsoever be prohibited
- 3 That there shall be a system of accurate and complete records filed in an accessible manner—a complete record being one which includes identification data cause of illness or injury nature and extent of illness or injury detailed description of physical findings special examinations such as consultations clinical laboratory and x-ray tentative or provisional diagnosis treatment prognosis with estimated period of disability progress of illness or injury final diagnosis, condition on discharge and results and such additional information as may be required by statute for Workmen's Compensation claims or for other purposes
- 4 That all patients requiring hospitalization shall be sent to institutions approved by the American College of Surgeons
- 5 That the medical department shall have general supervision over the sanitation of the plant and the health of all employees
- b Physicians and surgeons qualified as in paragraph 2 of the above minimum standard may properly be employed on a full time or a part time basis by industrial organizations to provide medical and surgical service for their employees as follows
 - i To provide emergency service and first aid in injury or disease and to provide adequate medical or surgical care for industrial injuries and diseases Medical and surgical care of the families of employees and of employees themselves except for emergency and industrial injuries and diseases should be provided by the industrial physician only in remote districts where other adequate medical service is not available
 - ii To provide pre-employment and periodic physical examinations
 - iii To study the hazards of the particular industry and to cooperate with other agencies in effecting such measures as may be needed for the prevention of injury and disease

- iv To keep accurate records such as may be required by local Workmen's Compensation laws, and so complete as to serve for scientific investigation of industrial hazards with a view to their further prevention These records are privileged communications, subject always to due process of law
- c The sale of a contract by an industrial organization to an individual physician or group of physicians for medical and/or hospital service for its employees encourages commercial competition and is to be condemned
- d Unethical practices in publicity advertising solicitation, and competition either of a professional or of a financial nature, must be eliminated
- e The accepted code of ethics of the medical profession which is designed to protect the best interests of the patient should apply to industrial medical service as to all other forms of medical practice

AN HONOR TO DR. HARVEY CUSHING

Among the honorary degrees awarded by Syracuse University, Dr Harvey Cushing of Yale University Medical School was the recipient of the degree of LL D

MORTALITY RATES

Telegraphic returns from 86 cities, with a total population of thirty-seven millions for the week ending June 2, indicate a mortality rate of 112 as against a rate of 100 for the corresponding week of last year. The highest rate (248) appears for Schenectady, N Y, and the lowest (59) for South Bend, Ind. The highest infant mortality rate (261) appears for San Antonio, Texas, and the lowest for Bridgeport, Conn., Duluth, Minn., Evansville, Ind., Louisville, Ky., South Bend, Ind., Syracuse, N Y, and Tampa, Fla., which reported no infant mortality.

The annual rate for 86 cities is 123 for the twenty two weeks of 1934, as against a rate of 117 for the corresponding period of the previous year.

EXTRACTS FROM THE JUNE BULLETIN OF THE
NATIONAL TUBERCULOSIS ASSOCIATION

DR DUNHAM, *President*

Dr Kennon Dunham of Cincinnati, whose work for many years in the field of x-ray diagnosis of tuberculosis has been outstanding, and who has contributed much to the whole movement, was elected president of the Association.

TRUDEAU MEDAL

The Trudeau medal was awarded to Dr William Snow Miller of Madison, Wisconsin. In announcing the award Dr Esmond R Long, chairman of the committee, spoke of Dr Miller's lifelong and outstanding research in the anatomy of the lung and chest.

TIMELY WARNINGS

Past experience has shown that the incidence of poliomyelitis is likely to begin in June and progress through the summer months.

The Fourth of July brings a crop of casualties which are largely preventable, and the mortality from drowning is now well underway.

The family physician may well warn parents of the dangers incident to warm weather and the vacation periods.

Although typhoid is a declining menace, there will be sporadic cases and there is always a danger from a carrier. The doctor may tell his families about those dangers, and give timely advice, especially urging early medical service in every case of illness.

CORRESPONDENCE

DISCUSSION OF AFFAIRS AT THE BOSTON
CITY HOSPITAL

June 11, 1934

Editor of the Journal,

Dear Sir,

The editorial in this issue of the *Journal*, relative to the Boston City Hospital, seems in conflict with the "Accepted Resolutions" of the Norfolk District Medical Society, and the Council, which by a unanimous vote accepted and approved said Resolutions.

The Finance Commission of Boston has done a notable work in bringing before the public the injustice that has been perpetrated, on the medical profession of Boston, by the Boston City Hospital.

The Committee from the Norfolk District was well aware of the unfair competition in the O P Dept. The Committee saw numbers of well-to-do people attend the Clinics, come in expensive cars, walk in and not pay a cent, and no questions asked, all at the expense of the taxpayers.

The irony of the affair is, that most of the doctors are taxpayers; they are supplying the wherewithal to destroy their own means of making a livelihood, and the doctors ministering to these well-to-do patients are destroying their own business as well as that of their fellows.

What an injustice it is to the taxpayers of Boston to have to support, in the hospital proper, patients who are perfectly able to pay politicians and their friends, clients of insurance companies who pay little or nothing for treatment and board.

When we consider the fact that the Boston City Hospital, in conjunction with some other hospitals in Boston, has about ruined the profession by unfair practices, and that much of the unfair competition has been done, outside the Charter of the City Hospital, that is illegally, it seems that the *Journal* should condemn such practices, instead of suggesting a legal means of continuing the present unjust course, as regards both the physician and the taxpayer.

SHALL WE WAIT FOR THE PUBLIC TO ACT?

Massachusetts General Hospital Boston

Editor, *New England Journal of Medicine*,

I am enclosing an editorial which I gleaned from Wednesday's *Cleveland Press*. It seems to me to be a thoroughly just and intelligent criticism of the official American Medical Association attitude. This attitude certainly bears a very striking resemblance to old guard Republicanism. It is a form of unenlightened standpointism thoroughly out of tune with the times. It is the kind of attitude that quite naturally leads the public to brand the American Medical Association the "Doctors Trust." Both the profession and the public are to be congratulated that in the *New England Journal* we have openmindedness and constructive leadership. Would that we might say the same of the national organ.

Sincerely yours,

J. H. MEANS, M.D.

June 15 1934

EDITORIAL

CONSERVATIVE DOCTORS

If the resolutions of the American Medical Association read somewhat like the resolutions of an old guard Republican campaign committee, it is for like reasons.

They wish the depression hadn't happened and they can hardly believe that it did. And they like to believe that if we just sit tight and let nature take its course nothing like it will ever happen again. They hope that the free play of economic forces will again make everybody prosperous—prosperous enough to pay their doctors bills, anyhow—and permanently prosperous, next time.

One can sympathize with the fear physicians feel toward any scheme in which government officials, politicians, insurance company executives or somebody would be bossing the doctors.

But how prevent the spread of public clinics, hospitals and insurance plans as long as millions of people cannot pay for medical care?

The doctors will not go so far as to say that all our public hospitals and public clinics now in existence ought to be abandoned. But they are reluctant to see them multiplied.

Perhaps it all comes down to one's view of the probabilities about the future volume of unemployment in America. For the time being the doctors who can afford to attend conventions prefer to believe that everybody is soon going to be prosperous again. They do not wish to see a permanent expansion of public institutions based on a temporary emergency.

If on the other hand the economic status of a very large fraction of the population is going to continue uncertain government will inevitably be drawn deeper into the effort to make that first essential—medical care in time of sickness—more certain through collective action.

To us it would seem wiser for the medical profession, instead of trying to preserve a status that has not actually existed for years to take the lead in formulating a plan whereby the burden of costs could be reduced or distributed without impairing the professional control of its own activities.

If the doctors wait until some one else forces a scheme upon them it may be less to their liking and less satisfactory in its results.—*Cleveland Press*

PUBLICITY OF MEDICAL MATTERS

St. Elizabeth's Hospital
736 Cambridge Street
Brighton, Mass.

May 29, 1934

Editor, *New England Journal of Medicine*

My attention was directed by the Committee on Ethics and Discipline, of the Massachusetts Medical Society, to an article published in the *Boston Herald* February 16, 1934, wherein my name appeared quite prominently in a medical "write-up."

This article was written by a young lady who three months previously presented herself at the Clinic and sought permission to remain as an observer. She said she had visited and observed in several hospitals being interested especially in reconstruction work.

I granted her permission to remain after I had first explained our standard of ethics as it pertains to publicity and had warned her that I was not to be quoted or my name used under any condition, in the public press. Further than this I had no knowledge or connection in any way with the publication of this article.

I am glad to support the Committee on Ethics and Discipline in its efforts to curb publicity and wish to state that I regret most sincerely this undesired publicity and that I am opposed to all forms of medical "write-ups."

Yours truly,

THOMAS J. BRODERICK, M.D.,
Orthopedic Department

A PROTEST AGAINST THE 'FREE ABSTRACT JOURNALS' PUBLICATIONS

Clinical Medicine and Surgery

June 6 1934

The Editor,

New England Journal of Medicine,

The time appears to have arrived when, if we do not want to see our living carried off before our eyes by commercial exploiters of the legitimate medical press we must make a concerted effort to stop it.

The so-called "Free Abstract Journals" (whose names are familiar to you) could not exist if they were unable to act as parasites upon the sound and scientific medical periodicals whose editors and publishers spend the time, brains and money to se-

lect, arrange and present the material which these people appropriate for their purposes

If these purveyors of predigested professional pabulum carry their plans to fruition—if we permit them to do it—we, who are depending for our livelihood upon furnishing the medical profession with information will find many of our subscribers and most of our advertisers leaving us for the pages of these sheets which could not live for one moment except upon us

I have forbidden the publishers of the periodicals to which I allude to reprint or abstract any original communications appearing in the pages of *Clinical Medicine and Surgery*, and am copyrighting each issue of our journal, beginning with the June, 1934, number. This will not affect you nor any other journal publishing original articles or having a paid subscription list. You may abstract from our pages as freely as you please. If the editors and publishers of most of the responsible and reputable medical journals in the country would do the same, we would have the situation well in hand.

What are your reactions to this suggestion?

May I count upon your support in this matter?

In what way or ways can I cooperate with you to make our positions in the medico-literary field secure from pirates?

Sincerely and fraternally yours,

GEORGE B LAKE, M.D.,

Editor and Publisher

P.S. My strictures do not apply to *Medical Economics*, which is a properly edited journal, publishing original material in its special field and not competing with us, except in the legitimate manner of an honorable contemporary.

REPORTS AND NOTICES OF MEETINGS

THE HARVARD MEDICAL SOCIETY

The Harvard Medical Society met in the amphitheatre of the Peter Bent Brigham Hospital on Tuesday, May 8, at 8 15 P.M. Dr. Walter B. Cannon presided. Following the presentation of clinical cases, some aspects of the peripheral vascular circulation were discussed by Drs. James C. White and Norman E. Freeman from the Surgical Service of the Massachusetts General Hospital.

The first clinical case was that of a boy who had been shown at a previous meeting. He had always been less active than his playmates and evidenced splenomegaly at the age of five. He experienced no real illness until March 20 of this year when a cough and intermittent fever developed. This was followed by severe repeated hematemeses at the second of which he entered the Peter Bent Brigham Hospital on the Medical Service. The spleen was palpable below the umbilicus. The red blood cell count was one and a half millions with a hemoglobin of 32 per cent. The white blood cell count was 6000.

He was treated for hemorrhage and subsequent anemia with iron and intramuscular liver extract. At the time of the meeting the red blood cell count had become essentially normal and the white blood cell count was 2500 with no abnormal cells present. The case was transferred to the surgical service for splenectomy.

The x-ray studies in this case are of especial interest. At entry the chest plates showed a picture of bronchopneumonia which may have been due to aspirated blood. A month later plates showed normal lung fields thereby eliminating tuberculosis. After ingestion of a thick barium mixture, the negative shadow of a rounded long object was demonstrated in the esophagus resembling a foreign body, which is the first case of varicose vein of the esophagus demonstrated by x-ray at this hospital. Dr. Sosman stressed the point that the film should be exposed from thirty to sixty seconds after administration of the thick barium so that the esophagus is merely coated with the radio-opaque substance.

The second case was that of a forty-five year old Italian housewife who first entered the hospital in November, 1932, with a history of swelling behind the left knee of three months duration. Sharp stabbing non-radiating pain had occurred in the same region five years previously. Treatment for neuritis had been instituted by a local doctor. A nodular mass the size of a lemon lay medially behind the left knee. There was reddening of the overlying skin. The chest plates were reported negative. A cystic mass was removed at operation which upon histological examination proved to be an hemangio-endothelioma. Following the operation a course of x-ray treatments was given.

In December, 1933, the patient returned to the hospital with a mass in the incisional scar, which later was observed to be fluctuating in size and tenderness. The patient was readmitted to the hospital shortly before the meeting. On examination, the mass in the site of the old scar was found freely movable above but fixed below. No lesions were observed in the groin, but x-ray examination revealed soft tissue shadows in the lateral portion of the right lung and the left apex which Dr. Sosman believes represent definite pulmonary metastases. Dr. Homans recalled a previous case in a boy and made the observation that tumors of this nature go on harmlessly for a long time only to become malignant after surgical intervention.

The first speaker of the evening was Dr. James C. White, who discussed 'Studies on the Innervation of the Vessels and Their Application to Neurovascular Surgery'. In reviewing the results in cases of Raynaud's disease in the Circulatory Clinic at the Massachusetts General Hospital, Dr. White pointed out that surgery has been most successful in relieving symptoms in the lower extremities by excision of the second to fourth lumbar sympathetic ganglia. Failure to relieve symptoms in the upper

extremities in the first fifteen cases was due to in complete sympathetic denervation followed by regeneration of the nerve fibers and return of symptoms after six to eight months. The possibility of regeneration was removed in the later operations for the condition by excision of the inferior cervical and the first two thoracic ganglia. After a short period of vasodilatation even these patients showed a skin temperature in the hands of 78° F (room temperature 70° F), while that of the feet after sympathetic denervation was 90° F in the same environmental temperature.

Dr White explained this phenomenon by T. R. Elcott's work done in England in 1905 and recently reemphasized by Dr Cannon. This has brought out the surprising fact that smooth muscle becomes sensitized to the action of adrenin after severance and degeneration of its postganglionic sympathetic neurones. The possibility that the denervated smooth muscle in the digital arterioles can be constricted by circulating hormones was first investigated by Smithwick, Freeman and White in patients after unilateral sympathetic denervation of the upper extremities for Raynaud's disease. Injections of adrenalin (1 to 200,000) produced a striking fall in the skin temperature of the previously denervated hand but no detectable fall in the limb with intact autonomic nerve supply. To test whether the patient secreted enough adrenin from his own glands to have any effect on the denervated sensitized blood vessels insulin was injected to produce a hypoglycemia which stimulates the sympathico-adrenal system. The same effect was observed as after the injection of adrenalin. More recently these observations have been repeated on rabbits in which one ear had been totally denervated. After a preliminary paralysis the denervated ear became hypersensitive to agents calling into play the sympathico-adrenal system. In addition the speaker reported that the phenomena of sensitization disappear almost entirely after extirpation of the adrenals. What remains of the effect may be due to the intrinsic tone of the blood vessels themselves and possibly to the action of sympathin.

Dr White further declared that studies similar to those mentioned above have revealed the fact that no sensitization of the lower extremities occurs comparable to that shown to exist in the upper extremities after sympathetic denervation. This he explained from an anatomical point of view. In the operation at present employed for sympathetic denervation of the upper extremities by the excision of the inferior cervical ganglion and the first two thoracic ganglia, the surgeon removes cell bodies for the entire postganglionic nerve supply to the upper extremities except for a few fibers entering the brachial plexus through the fifth cervical nerve. Hence practically the entire vascular supply of the hand is sensitized to the action of adrenin after time has been allowed for degeneration of the nerve fibers. In the lower extremity however removal of

the second to fourth lumbar ganglia destroys only the preganglionic fibers supplying the leg via the anterior femoral and obturator nerves. The cell bodies for the postganglionic fibers in the sciatic nerve, which is the important supply to the foot, are located in the fourth lumbar to third sacral ganglia. Thus lumbar ganglionectomy essentially interrupts only the preganglionic innervation of the lower leg.

Dr White concluded his address with the suggestion that section of the preganglionic fibers to the upper extremity might be obtained by cutting the upper anterior thoracic roots. This should lead to paralysis of only a part of the intercostal muscles. He is at present planning to investigate this procedure in the rabbit.*

Dr Norman E. Freeman, the second speaker, spoke on 'Factors Controlling the Peripheral Blood Flow in Man'. A modification of the method of Hewitt and Van Zwaluwenburg was used to determine the blood flow in the hand. The apparatus is built on the plethysmograph principle the cylinders being modified calorimeters in which the temperature can be kept constant within very narrow limits. In measuring the blood flow in human hands the venous return from the hand is obstructed at the wrist by a modified blood pressure cuff by which the pressure is kept just below diastolic. The hands are inserted into the calorimeter and the change in hand volume per unit of time recorded on a smoked drum through a closed lever system. While records are being taken emotional disturbances, noise, pain and worry must be eliminated because they reduce the peripheral flow very significantly. The patient must also be in basal condition with respect to digestion and exercise.

By means of lantern slides Dr Freeman showed the various well known vasomotor reflexes mediated through the sympathetic nervous system such as a diminished blood flow when too rapid a loss of heat was threatened and an increased blood flow on heating the body whether by the application of external heat or by increasing the internal metabolism through dinitrophenol.

In Raynaud's disease Dr Freeman showed an increase in blood flow in the affected hand after novocaine block of the sympathetic nerves even though the temperature of the hand was maintained at a low level. The blood flow in the completely sympathetomized hand immediately after operation is at a high level and is influenced very little by local changes in temperature. Some time later, however, the blood flow varies directly with the local temperature. It was shown that the rate of blood flow was a function of temperature according to laws of chemical reactions.

Dr Freeman also made the interesting observation that by exercising the hand for two minutes or

*Since the meeting it has been found that after section of the preganglionic neurones in the upper thoracic anterior spinal roots the vessels in rabbit's ear remain in a constant state of vasodilatation. After this operation the arteries are no longer affected by hormones circulating in the blood stream.

by occluding its blood supply for ten minutes, a blood flow debt was incurred by the tissues which was subsequently paid by a proportionately increased blood flow in the hand. From previous work on the effect of decreased oxygen concentrations on the tone of arteries, it seems that increased blood flow is probably due to an oxygen debt rather than to the accumulation of metabolites locally.

Dr Freeman was able to make a quantitative analysis of the blood flow in a sympathectomized hand at different temperatures. If at a certain temperature of the hand a tourniquet was applied for five minutes and again for ten minutes, following the release of the tourniquet, the excess blood flow above the basal flow after the ten minute occlusion was double that following the five-minute occlusion. Again, if the basal flow at three different temperatures was determined and a blood flow debt of ten minutes created by occlusion of the circulation at each temperature, the excess blood flow at each temperature was equal, within the experimental limits, to the size of the debt.

In conclusion, the speaker pointed out that the function of the peripheral blood flow from the point of view of general bodily economy is to regulate the temperature of the body. It is estimated that 85 per cent of the body heat is dissipated by the extremities reflexly. After sympathetic denervation, however, the peripheral blood flow is apparently determined by the actual needs of the local tissues. With these facts in mind, it becomes illogical to apply local heat in cases of peripheral vascular disease such as diabetic arteriosclerosis and thromboangiitis obliterans in which the vascular supply to the extremities is incompetent, because heat would merely increase the demand for a greater rate of blood flow. It is often observed clinically that such patients complain of pain when heat is applied to the extremities.

Following a discussion by Drs Drinker, Homans, and Cutler, the meeting was adjourned.

PLYMOUTH DISTRICT MEDICAL SOCIETY

A stated meeting of the Plymouth District Medical Society was held at the Brockton Hospital, May 17, 1934. The meeting was called to order by the President, Dr Alley, at 11 15 A.M. The minutes of the last meeting were read and approved.

The President then turned the meeting over to Dr Barrett who had charge of the literary program prepared by the Staff of the Hospital. A series of short clinical papers was presented by members of the Brockton Hospital Staff.

Dr Loring Packard demonstrated a series of x ray films, showing the normal anatomy of the heart and lungs and a number of unusual pathological conditions.

Dr J. R. Noyes showed a patient who entered with such a severe fracture of all bones of the face that the hard palate was mobile. This had been immobilized with traction from a metal and plaster

head band to a bar in the mouth with an excellent cosmetic result and good dental approximation.

Dr W. S. Walker presented a patient forty-two years of age with severe cretinism, anemia, and abnormal uterine bleeding. He discussed the not uncommon association of hypothyroidism and abnormal uterine bleeding and also pointed out the danger of giving morphine to patients with myxedema or cretinism.

Dr George A. Buckley discussed several fracture cases, pointing out among other things that persistent pain may well be an indication of poor reduction. One patient was first seen several years ago with a fracture of both bones of one leg. He was treated in the usual conservative manner, the result was excellent but his convalescence very long. He came back six months ago with a similar fracture of the other leg and this time he was given early baking and massage, thereby halving his period of disability.

Drs C. D. McCann and B. Bornstein discussed the management of functional menorrhagia with endocrine products, pointing out the relationship of Prolan A and Prolan B to follicle ripening and corpus luteum development respectively and their relationship to the changes in the uterine mucosa during the menstrual cycle.

Dr F. F. Weiner demonstrated pyelograms of an unusual case of bilateral complete duplication of the ureters in a patient with a large dermoid cyst.

He also outlined the management of syphilis in the Brockton Hospital Clinic stressing (1) the importance of early diagnosis during the primary and secondary stages by darkfield examination, (2) the need of approximately two years of continuous treatment in early syphilis, (3) the necessity of routine lumbar puncture, and (4) continuance of treatment for an adequate length of time even in face of a negative serology.

FAULKNER HOSPITAL CLINICAL MEETING

The regular monthly clinical meeting of the Staff of the Faulkner Hospital was held at the hospital on Thursday, June 7, at 5 00 P.M.

Two of the cases which had come to autopsy during the month were presented for discussion.

One was a case of cardiac decompensation with a history of having had what might have been a coronary occlusion some years before. There had also been hypertension and a period of cardiac decompensation in the past. There was a positive Wassermann. There were murmurs suggesting involvement of the aortic valve and auricular fibrillation was also present. The point of clinical interest was what type of lesion would be found in the heart. The signs of involvement of the aortic valve with a positive Wassermann reaction in the blood made it seem likely that a heart worn out by working with the handicap of injury to the aortic valve due to syphilis would be found. On the other hand auricular fibrillation in such conditions is unlikely, and

also a heart which has once decompensated with such a lesion usually does not recover. In addition to the disturbance in the heart there had just before death developed a hemiplegia presumably due to an embolus from a mural thrombus and there was evidence of chronic nephritis of the vascular type. The autopsy showed that vascular disease of the arteriosclerotic type rather than syphilis had been the main factor in causing the cardiac decompensation. There was a mural thrombus in the left ventricle.

The other case was one in which evidence of pyloric obstruction existed with a history of hematemesis on two occasions during the ten months preceding death. The x-ray studies showed some type of lesion in the duodenum which was thought to be the scarring of an old ulcer. There was a dilated stomach and some spasm of the pylorus but not complete obstruction at the pylorus. The patient was losing weight and was somewhat anemic. The other physical finding of interest was a hard mass completely surrounding the rectum at its lowest point. This patient had been under observation earlier in the year and at that time this hard mass did not surround the bowel and seemed to be attached to one corner of the prostate. There was no retention of urine. On proctoscopic examination there was no evidence of ulceration of the mucous membrane of the bowel and an attempt to obtain a biopsy did not help because only normal mucous membrane was removed. Because the pyloric obstruction could not be established as due to malignant disease, exploration was advised and carried out. The patient did not survive the operation more than a few hours and the operation and partial postmortem examination showed a diffuse neoplasm presumably a lymphoblastoma involving the duodenum, other parts of the gastro-intestinal tract and invading the perirectal tissues. Had the patient survived it is possible that x-ray therapy might have been beneficial temporarily.

Dr. Edward L. Young, Jr., then talked about difficulties in the diagnosis of disease of the gallbladder and called attention to some of the peculiarities in the localization of the symptoms and emphasized in just what manner the x-ray studies and the Graham test should be used in reaching conclusions. He also called attention to the importance of seeing the patient during the attack in certain diseases of the gallbladder. He mentioned two cases in which the pain and discomfort were localized under the left costal border instead of the right. He cited cases in which the gallbladder according to the Graham test functioned normally but still at operation showed pronounced chronic inflammation in the wall and emphasized the fact that this test, after all, only shows the function of the gallbladder so far as receiving bile and discharging it again, and does not necessarily demonstrate disease of the gallbladder. He also called attention to the fact that there seems to be definite evidence that bile containing the dye and throwing a shadow may accumulate in the

duodenum giving an appearance suggesting a gall bladder and, after a fat meal may disappear from the duodenum giving the impression that there is a gallbladder functioning properly.

This meeting completes the series of meetings for the winter season of 1933-1934. The attendance and interest in these meetings have been such that the Staff feels that another series of meetings should be scheduled for the coming winter. Therefore, a schedule of the Faulkner Hospital Clinical Meetings for the winter season of 1934-1935 will be announced in September.

MEDICAL LIBRARY ASSOCIATION

The thirty-sixth annual meeting of the Medical Library Association was held in Baltimore, Md., May 21 to 24, inclusive, under the presidency of Miss Marcia C. Noyes, Librarian of the Medical and Chirurgical Faculty of the State of Maryland.

The next annual meeting will be held in Rochester, N. Y. in June, 1935.

The following officers were elected for 1934-35:

President: Mr. Charles Frankenberger, Librarian, Medical Society of the County of Kings and Academy of Medicine of Brooklyn, Brooklyn, N. Y.

Vice President: Miss Louise Ophuls, Librarian, Lane Medical Library, San Francisco, Cal.

Secretary: Miss Frances N. A. Whitman, Librarian, Harvard University Schools of Medicine and Public Health, Boston, Mass.

Treasurer: Miss Mary Louise Marshall, Librarian, Tulane University Medical School, New Orleans, La.

Chairman, Executive Committee: Miss Marjorie J. Darrach, Librarian, Medical Science Department, Detroit Public Library, Detroit, Mich.

Editor of the 'Bulletin': Mr. J. C. Harding, Librarian, Cleveland Medical Library Association, Cleveland, Ohio.

Manager of Exchange: Miss Ella B. Lawrence, Librarian, Washington University School of Medicine, St. Louis, Mo.

INTERNATIONAL ASSOCIATION FOR PREVENTIVE PEDIATRICS

The Fourth Conference of the International Association of Preventive Pediatrics (medical section of the Save the Children International Union) will this year be held at Lyons, Thursday, and Friday, September 27-28.

The subjects to be discussed and the names of the rapporteurs are as follows:

(1) The Prophylaxis of Malaria in Children. Prof. Cacace, Naples, and Prof. Gillot, Algiers, with whom will be associated Dr. Larrony (a British rapporteur will be named later).

(2) The Prophylaxis of Rickets and Convulsions. Prof. Adam, Dantzig, and Prof. Monrad, Copenhagen.

Those who desire to be present at the Conference, as well as take part in the discussions following

the reports, are requested to communicate with the Secretary of the I A P P, 15 rue Lévrier, Geneva (Switzerland)

THE AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians will hold its Nineteenth Annual Clinical Session in Philadelphia, April 29 May 3, 1935

Announcement of these dates is made particularly with a view not only of apprising physicians generally of the meeting, but also to prevent conflicting dates with other societies that are now arranging their 1935 meetings

Jonathan C Meakins of Montreal, Que., is President of the American College of Physicians, and will arrange the Program of General Sessions. Dr Alfred Stengel, Vice-President in Charge of Medical Affairs of the University of Pennsylvania, has been appointed General Chairman of local arrangements, and will be in charge of the Program of Clinics. Mr E. R. Loveland, Executive Secretary, 133 135 South 36th Street, Philadelphia, Pa., is in charge of general and business arrangements, and may be addressed concerning any feature of the forthcoming Session

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

July 24-31—The IVth International Congress of Radiology will be held in Zurich under the presidency of Professor H. R. Schnitz. General Secretary Dr H. E. Walther, Gloriastrasse 14 Zurich

August 18 September 30—Medical Study Trip to Hungary. See page 975 issue of May 10

September 3-6—American Public Health Association at Pasadena, California. Dr J. D. Dunshie, Chairman Local Committee on Arrangements

September 4, 6, 6—International Union Against Tuberculosis. For information address the National Tuberculosis Association, 460 Seventh Avenue New York City

September 10, 11, 12, and 13—American Congress on Physical Therapy will meet in Philadelphia at the Bellevue Stratford. For details write American Congress of Physical Therapy, 30 North Michigan Avenue Chicago Illinois

September 10-15—First International Congress of Electro-Radiobiology will be held in the Doges Palace at Venice. For details address the General Secretary of the Congress Dr Giocondo Protti S. Gregorio 173 Venice (Italy)

September 27 and 28—International Association for Preventive Pediatrics. See page 1353

September 28-29—New England Surgical Society will meet at Burlington, Vermont. For details address the Secretary Dr John M. Birnle, 14 Chestnut Street Springfield, Mass

October 22 November 2—1934 Graduate Fortnight of the New York Academy of Medicine. See page 1240 issue of June 7

October 31 - November 2—Massachusetts State Nurses Association Hotel Statler, Boston. For information write Miss Helene G. Lee R.N. 420 Boylston Street Boston

April 29 May 3, 1935—The American College of Physicians. See notice above

June, 1935—Medical Library Association. See page 1353

BOOK REVIEWS

Human Embryology and Morphology. By Sir Arthur Keith. Fifth Edition. 558 pp. Baltimore: William Wood and Company. \$10.00

The fifth edition of this book the first of which appeared thirty-two years ago, takes cognizance not

only of the orthodox systematic and descriptive embryology, but also takes into consideration many of the newer advances made by the application of experimental methods to embryology. While adequate for the purposes of the student and the practitioner in description of embryological processes and of anatomic detail, nevertheless the book avoids an unwieldy size. A note from the authors' preface might well register with more of our scientific writers. It says "There is one danger to which successful textbooks are particularly exposed in these times. It is the danger of overgrowth. Dominant stocks of animals have been hurried to extinction in past geological ages because their bodies became so big as to be unwieldy. I have seen most valuable and prosperous textbooks killed by overgrowth."

This clearly written volume is adequately illustrated by a number of well-chosen diagrams. In the discussion of the development of various parts of the body, adequate attention is placed on points of clinical significance, such as malformation. This book may well be considered a distinct addition to any physician's library.

Text Book of Pathology. By Robert Muir. Third Edition. 957 pp. Baltimore: William Wood and Company. \$10.00

This textbook is one of the standard English works on pathology and has many commendable features. However, it finds stiff competition from the best of the American textbooks and particularly is at a disadvantage as compared with the excellent text of Boyd of Winnipeg. The small yet adequate size of the illustrations is a feature that should do much to reduce the cost of the book and might well be followed by some of our own writers.

Adequate emphasis is laid on gross pathology without neglecting histologic detail.

With the treatment of some subjects the reviewer is not in sympathy, as for example arteriosclerosis. Here Muir sharply divides the atheromatous type from other types of arteriosclerosis, excluding it from the classification of arteriosclerosis. The statement that calcification of the media is a frequent occurrence in the abdominal aorta is certainly not in keeping with experience here. The division of arteriosclerosis into that secondary to nephritis and primary arteriosclerosis is unusual.

The discussion of Paget's disease of bone and osteitis fibrosa cystica is rather disappointing. The section on bone tumors is also a bit inadequate.

The style is very pleasant, clear and readable, and no doubt contributes to the intrinsic worth that has led this textbook to its third edition.

The index leaves much to be desired. Thus, the only mention of carbon monoxide in the index leads one to the statement that "Lorrain Smith found by means of the carbon monoxide method that the blood volume in cases of chlorosis was greatly increased."

The record of the last meeting was read in abstract by the Secretary, and as no omissions or corrections were noted it was accepted as read and as published in the "Proceedings" in the official organ of the Society. The President read obituaries of three Councilors who had died recently as follows

Since the last meeting of the Council death has taken from us three of our members

DR. THOMAS HENRY O TOOLE died at his home in Norwood on April 4 1934 at the age of sixty two. He was born in Clinton Massachusetts, but moved to Philadelphia Pennsylvania, where he received his early education later being graduated from Johns Hopkins University and Jefferson Medical College of Philadelphia in 1897. He settled in Norwood where he practiced for thirty five years.

Dr O Toole joined the Massachusetts Medical Society in 1922 and was a member of the Council at

the reports, are requested to communicate with the Secretary of the I A P P, 15 rue Lévrier, Geneva (Switzerland)

6 That Dr Charles William Jackson of Monson a retired Fellow be nominated to the House of Delegates for Affiliate Fellowship in the American Medical Association

DAVID N BLAKELY *Chairman*

He then offered his committee's report on Finance and it was adopted

REPORT OF THE COMMITTEE ON MEMBERSHIP AND
FINANCE ON FINANCE

This Committee recommends that the surety bond of the Treasurer for \$15 000 which expires June 19 1934 be renewed for one year from that date

DAVID N BLAKELY *Chairman*

Reports on three petitions for restoration to the privileges of fellowship were read by the Secretary as follows for E J Grainger, F S Bennett and W B Riley Each recommended that the petitioner be restored under the usual conditions and each was accepted by vote The report of a committee composed of Richard Collins, H Q Gallupe, and F Van Nûrs, recommending that the petition of I F Armstrong of Hudson be restored, had been referred to the Standing Committee on Ethics and Discipline by the Council February 7, 1934 for an opinion That committee, at a meeting on February 20, 1934, had reported that the report of the committee headed by Dr Richard Collins in the case of I F Armstrong be approved On being put to a vote Dr Armstrong was restored under the customary conditions

Petitions for restoration were received and committees to consider them appointed as follows

For P R Oeser

J F Burnham J F Howard W C Farley

For P J O Day

R. A. Rice F H Thompson Jr., T R Donovan

For H S Queen

G E Emery E R Leib R J Ward

For G L Lemaitre

E E Cyr, N J Scarito E H Ganley

The Treasurer presented the following report, and it was accepted by vote

REPORT OF THE TREASURER

Regarding the finances of the Society for the first five months of this year that is from January 1 to June 2 1934 the treasurer reports as follows

Annual dues resident and nonresident, received by the treasurer total \$38 736 This is an increase of more than \$3900 over the corresponding five months of 1933 the period you will recall of the "banking holiday" with bank failures Income from securities of General Fund is \$1743 which is a small increase over the corresponding months of 1933 Income from Building Fund is \$934 compared with \$947 for the five months of 1933 You may recall also that defaults came in 1933 in interest of two securities held in the Building Fund

The Committee on Postgraduate Medical Instruction began the year with a cash balance of \$2750

and the Council voted an additional appropriation of \$1000 for expenses This Committee ends the period to this June with a cash balance of about \$3200 available for 1934 1935 activities

In general our Securities (bonds and notes) have shown further appreciation in market values during this year indeed on several issues prices are now abnormally high During the first five months of this fiscal year when surplus cash accumulated from assessments the treasurer in order to bring in some income for the Society has bought a number of short term securities yielding from 1¼ to 3½ per cent He has also bought additional United States Government notes and other bonds for longer investment In his opinion it is becoming more difficult to invest wisely our funds owing to uncertainties in the outlook for securities

There has been only one unusual expense not large due to the coöperation of our Society with the Civil Works Administration of Massachusetts and the Federal Emergency Relief Administration

CHARLES S BUTLER, *Treasurer*

Dr A S Begg, Norfolk a member of the Committee to revise the By-Laws spoke as follows

Mr. President and Gentlemen as you will remember the Committee to revise the By-Laws was appointed at the October meeting of the Council It held a series of meetings and presented at the February meeting a report At that February meeting there were a number of suggestions made although the Committee had attempted to get suggestions in before the meeting, those were rather slow in coming and finally the Council at the February meeting voted to refer this report back to the Committee This was done, and following the February meeting Dr Cheever, chairman had a letter in the *New England Journal of Medicine* asking for suggestions He also wrote to the presidents and secretaries of the various District Societies asking for suggestions and we had our final meeting at the very last possible moment so that we could get the report out for this particular meeting to-day

We have received a number of suggestions which we have carefully considered, and some of these have been included in this new draft, and some of them for various reasons were not included This report which we now present contains two typographical errors that have been called to our attention One of these is simply in the spelling of a word—on page 6 In the word "governed" The "e" and "n" should be interchanged And in Section 7 on page 5 the word "blanks" appears in two places and this should be changed to read "forms"—"printed forms" instead of "printed blanks" Those two corrections have been made in the By-Laws as they are now submitted

A COUNCILOR There is one additional typographical error on page 6 Section 1 where it says "The Council shall consist" The second "s" is left out of "consist"

the time of his death. He was a Fellow of the American Medical Association.

He is survived by his widow, a daughter and a son, Dr Thomas Henry O Toole, who is a Fellow of the Massachusetts Medical Society

DR. STEPHEN ANDREW MAHONEY SR died at his home in Holyoke on March 30, 1934, of a heart attack. He was born in North Brookfield in 1863. His pre-medical education was acquired at Holy Cross College where he was given the degree of Bachelor of Arts in 1885. His medical degree was conferred by the Harvard Medical School in 1889.

He began practice in Holyoke and in 1892 was appointed City Physician and a member of the Board of Health Survey serving until 1894. After a few years of general practice he devoted his major interest to surgery and in later years restricted his work to this specialty. Dr Mahoney was surgeon on the staffs of the Holyoke City and Providence Hospitals and was also Chief of Staff of the Memorial Clinic in Holyoke.

Dr Mahoney joined the Massachusetts Medical Society in 1888 was a member of the Council for many years taking an active part in the debates at meetings. He was also a member of the New England Surgical Society and a Fellow of the American Medical Association.

He is survived by his widow, two sons, one daughter and a sister. One son, Dr Stephen A Mahoney, is a Fellow of the Massachusetts Medical Society.

DR WILLIAM HOWARD ENSWORTH died at his home in East Boston May 3, 1934. He was born in East Boston, October 13, 1865. His early education was acquired in the schools of East Boston, he was graduated in medicine from the Harvard Medical School in 1888 and joined the Massachusetts Medical Society in that year. He was a member of the Council at the time of his death and a Fellow of the American Medical Association. At the meetings of the Council he took part in the debates and always showed an active interest in the proceedings.

Dr Ensworth is survived by a sister and a nephew.

The Secretary read the names of the Nominating Committee by Districts and the following responded to their names and retired to make a list of nominations:

Barnstable W D Kinney, *Berkshire* H J Downey, *Bristol North* W H Allen, *Bristol South* E F Cody, *Essex North* J F Burnham, *Hampden* G L Schadt, *Hampshire* J G Hanson, *Middlesex East* R R Stratton, *Middlesex South* A W Dudley, *Norfolk* T J Murphy, *Norfolk South* C S Adams, *Plymouth* T H McCarthy, *Suffolk* Lincoln Davis, *Worcester* David Harrower, *Worcester North* H R Nye.

Dr D N Blakely, Norfolk, presented the report of the Committee on Membership and Finance, on Membership, as follows and it was adopted.

Human Embryology and Morphology MEMBERSHIP AND
Keith Fifth Edition 558 pp
Ham Wood and Company \$10 00

The fifth edition of this book the ^{SEVENTEEN} Fellows be
appeared thirty two years ago, takes as of Chapter I,

- 1 Baker Harry Beecher, Taunton with remission of dues 1932, 1933, 1934
- 2 Bruce, Daniel Angus Atlantic (Quincy) with remission of dues 1934
- 3 Colby, Fred Bennett, Rangeley, Maine, with remission of dues 1933 1934
- 4 Dewey, Charles, Gipson, Dorchester
- 5 Dion Thomas Joseph Quincy, with remission of dues, 1934
- 6 Duckering William West, Dorchester
- 7 Granger Karle Henry, South Weymouth, with remission of dues 1934
- 8 Jackson, Alton Atwell, Everett.
- 9 Martin George Forrest, Lowell
- 10 Pillsbury, Ernest Dean Sunmount N Y with remission of dues, 1934
- 11 Robinson William Henry, Jamaica Plain, with remission of dues, 1934
- 12 White, William Allen, Roxbury
- 13 Whiting George Washington Whitney, Medford with remission of dues, 1934
- 14 Wilson, Charles Oscar, Lowell with remission of dues 1934

2 That dues of the following named two Fellows be remitted under the provisions of Chapter I, Section 6, of the By Laws

- 1 Brindisi Rocco Boston 1934

6 That Dr Charles William Jackson of Monson a retired Fellow be nominated to the House of Delegates for Affiliate Fellowship in the American Medical Association

DAVID N. BLAKELY *Chairman*

He then offered his committee's report on Finance and it was adopted

REPORT OF THE COMMITTEE ON MEMBERSHIP AND FINANCE ON FINANCE

This Committee recommends that the surety bond of the Treasurer for \$15 000 which expires June 19 1934, be renewed for one year from that date

DAVID N. BLAKELY *Chairman*

Reports on three petitions for restoration to the privileges of fellowship were read by the Secretary as follows for E. J. Grainger, F. S. Bennett and W. B. Riley. Each recommended that the petitioner be restored under the usual conditions, and each was accepted by vote. The report of a committee composed of Richard Collins, H. Q. Gallupe, and F. Van Nuys, recommending that the petition of I. F. Armstrong of Hudson be restored, had been referred to the Standing Committee on Ethics and Discipline by the Council, February 7, 1934 for an opinion. That committee, at a meeting on February 20, 1934, had reported that the report of the committee headed by Dr. Richard Collins in the case of I. F. Armstrong be approved. On being put to a vote Dr. Armstrong was restored under the customary conditions.

Petitions for restoration were received and committees to consider them appointed as follows

For P. R. Oeser

J. F. Burnham J. F. Howard W. C. Farley

For P. J. O'Day

R. A. Rice F. H. Thompson Jr., T. R. Donovan

For H. S. Queen

G. E. Emery E. R. Leib R. J. Ward

For G. L. Lemaître

E. E. Cyr, N. J. Scarito E. H. Ganley

The Treasurer presented the following report, and it was accepted by vote

REPORT OF THE TREASURER

Regarding the finances of the Society, for the first five months of this year that is from January 1 to June 2 1934 the treasurer reports as follows

Annual dues resident and non resident received by the treasurer total \$38 736. This is an increase of more than \$3900 over the corresponding five months of 1933 the period you will recall of the banking holiday with bank failures. Income from securities of General Fund is \$1743 which is a small increase over the corresponding months of 1933. Income from Building Fund is \$934 compared with \$947 for the five months of 1933. You may recall also that defaults came in 1933 in interest of two securities held in the Building Fund.

The Committee on Postgraduate Medical Instruction began the year with a cash balance of \$2750

and the Council voted an additional appropriation of \$1000 for expenses. This Committee ends the period to this June with a cash balance of about \$3200 available for 1934-1935 activities.

In general our Securities (bonds and notes) have shown further appreciation in market values during this year. Indeed on several issues, prices are now abnormally high. During the first five months of this fiscal year when surplus cash accumulated from assessments the treasurer in order to bring in some income for the Society has bought a number of short term securities yielding from 1½ to 3½ per cent. He has also bought additional United States Government notes and other bonds for longer investment. In his opinion it is becoming more difficult to invest wisely our funds owing to uncertainties in the outlook for securities.

There has been only one unusual expense, not large due to the cooperation of our Society with the Civil Works Administration of Massachusetts and the Federal Emergency Relief Administration.

CHARLES S. BUTLER, *Treasurer*

Dr. A. S. Begg, Norfolk, a member of the Committee to revise the By-Laws spoke as follows

Mr. President and Gentlemen, as you will remember, the Committee to revise the By-Laws was appointed at the October meeting of the Council. It held a series of meetings and presented at the February meeting a report. At that February meeting there were a number of suggestions made, although the Committee had attempted to get suggestions in before the meeting, those were rather slow in coming, and finally the Council at the February meeting voted to refer this report back to the Committee. This was done, and following the February meeting, Dr. Cheever, chairman, had a letter in the *New England Journal of Medicine* asking for suggestions. He also wrote to the presidents and secretaries of the various District Societies, asking for suggestions, and we had our final meeting at the very last possible moment so that we could get the report out for this particular meeting to-day.

We have received a number of suggestions, which we have carefully considered, and some of these have been included in this new draft, and some of them for various reasons were not included. This report which we now present contains two typographical errors that have been called to our attention. One of these is simply in the spelling of a word—on page 6. In the word "governed" the "e" and "n" should be interchanged. And in Section 7 on page 5 the word "blanks" appears in two places, and this should be changed to read "forms"—"printed forms" instead of "printed blanks". Those two corrections have been made in the By-Laws as they are now submitted.

A COUNCILOR. There is one additional typographical error on page 6 Section 1 where it says, "The Council shall consist". The second "s" is left out of "consist".

the time of his death. He was a Fellow of the American Medical Association.

He is survived by his widow, a daughter and a son, Dr. Thomas Henry O'Toole, who is a Fellow of the Massachusetts Medical Society.

DR. STEPHEN ANDREW MAHONEY SR. died at his home in Holyoke on March 30, 1934, of a heart attack. He was born in North Brookfield in 1863. His pre-medical education was acquired at Holy Cross College where he was given the degree of Bachelor of Arts in 1885. His medical degree was conferred by the Harvard Medical School in 1889.

He began practice in Holyoke and in 1892 was appointed City Physician and a member of the Board of Health Survey, serving until 1894. After a few years of general practice he devoted his major interest to surgery and in later years restricted his work to this specialty. Dr. Mahoney was surgeon on the staffs of the Holyoke City and Providence Hospitals and was also Chief of Staff of the Memorial Clinic in Holyoke.

Dr. Mahoney joined the Massachusetts Medical Society in 1888, was a member of the Council for many years taking an active part in the debates at meetings. He was also a member of the New England Surgical Society and a Fellow of the American Medical Association.

He is survived by his widow, two sons, one daughter and a sister. One son, Dr. Stephen A. Mahoney, is a Fellow of the Massachusetts Medical Society.

DR. WILLIAM HOWARD ENSWORTH died at his home in East Boston May 3, 1934. He was born in East Boston, October 13, 1865. His early education was acquired in the schools of East Boston. He was graduated in medicine from the Harvard Medical School in 1888 and joined the Massachusetts Medical Society in that year. He was a member of the Council at the time of his death and a Fellow of the American Medical Association. At the meetings of the Council he took part in the debates and always showed an active interest in the proceedings.

Dr. Ensworth is survived by a sister and a nephew.

The Secretary read the names of the Nominating Committee by Districts and the following responded to their names and retired to make a list of nominations:

Barnstable W D Kinney, *Berkshire* H J Downey, *Bristol North* W H Allen, *Bristol South* E F Cody, *Essex North* J F Burnham, *Hampden* G L Schadt, *Hampshire* J G Hanson, *Middlesex East* R R Stratton, *Middlesex South* A W Dudley, *Norfolk* T J Murphy, *Norfolk South* C S Adams, *Plymouth* T H McCarthy, *Suffolk* Lincoln Davis, *Worcester* David Harrower, *Worcester North* H R Nye.

Dr. D N Blakely, Norfolk, presented the report of the Committee on Membership and Finance on Membership, as follows and it was adopted: Its recommendations adopted.

Human Embryology and Morphology MEMBERSHIP AND

One from Worcester to Worcester North

- *1 Bassow, George Joseph Athol

Transferred to Worcester June 5 1934

consist of members in each of the eighteen districts. He thought that to get together nineteen men and try to accomplish anything would not be feasible, and he thought that the present Committee on State and National Legislation was not necessarily concentrated about Boston. Certainly it had one member from Worcester.

Dr J W Bartol, Suffolk, spoke of his experience on three different committees to revise the By-Laws, the last one reporting in this very room six years ago to a day, when the By-Laws of 1928 were approved by the Council. The present committee to revise the By-Laws began its work last October, and brought in a careful revision. Many suggestions were given at the meeting last February. All Fellows had been urged to make suggestions, both by a letter in the *Journal* and by correspondence with the officers of the Society and of the District Societies. He thought that the By-Laws as presented by the Committee, with any minor changes that might be presented, ought to be approved by the Council at once, that if there were any amendments later, they could be taken care of in the customary manner by the provisions of Chapter IX of the By-Laws.

Dr C E Mongan, Middlesex South, offered an amendment as follows. On page 5 in Section 5, beginning "Councilors in number equal to one for every thirty active and retired fellows and a majority fraction thereof, as of January first," he would like to amend that by substituting the word "twenty" for "thirty."

Dr T H McCarthy, Plymouth, said that the Plymouth District had instructed him to move to modify the representation of Councilors from one in thirty to one in twenty-five, but he did not care to amend Doctor Mongan's motion. The amendment was seconded and put to a vote and passed. Doctor Watts' amendment was put to a voice vote and not accepted. On a rising vote it was plain that the noes prevailed by a sizable majority.

Dr J F Burnham, Essex North, spoke as follows:

Chapter VI, Section 3, the sixth paragraph of the amended By-Laws reads as follows:

"Under the direction of the Committee on Publications he (the secretary) shall issue annually, as soon as possible after the first of January, to the officers of the general Society, of the District Societies, to the Councilors, and to such other Fellows in good standing as make application at the headquarters of the Society, a directory of the officers and Fellows of the Society."

That supersedes the words "sent to the Fellows who are not in arrears." That, as you see, limits the distribution of our directory very, very much, and I think it is an error. I think the men in the trenches should be recognized

For many years we have had a directory which is the best directory of any published by any State Society in the United States and is a wonderful credit to our Secretary. [Applause] It should be in the hands of every man who pays his dues.

Some of the reasons are: First, it will help a man who sends a case to another town to be able to send it to a Fellow of the Society. If a man wishes to call a consultant, he can call a consultant from that list with more certainty than he can call from a list that contains every doctor who may be in Massachusetts. It is a splendid advertisement of our Society.

We know there is some complaint among the men in the trenches that the Society is not doing much for them. We who are on the inside all know that that is not the fact. But here is one definite evidence that can be brought up that the Society has struck away one of the privileges which it has given to the practitioners throughout the State ever since the directory was published.

Doctor Begg stated that his committee had received the suggestions about the Directory and that they did not wish to see it abandoned, but were trying to save money for the Society by restricting the distribution. Doctor Burnham's motion having been seconded was passed by a unanimous vote.

The By-Laws as thus amended were approved without dissent.

The Nominating Committee having placed the following names on the blackboard and there being no further nominations from the floor, on motion duly seconded, the Councilors were requested not to vote and the Secretary to cast one ballot for the names on the blackboard:

For President William H Robey, Boston
For Vice-President Philemon E Truesdale, Fall River
For Secretary Walter L Burrage, Brookline
For Treasurer Charles S Butler, Boston
For Orator Brace W Paddock, Pittsfield

The Secretary having cast the ballot, the President announced the above officers and orator elected.

The Council adjourned for the Cotting Luncheon at 1:10 P.M.

The Council reassembled in the same room at 2:00 P.M., President Robey in the chair. Dr R I Lee, Suffolk, Chairman of the Committee on Publications, presented an informal report, saying that the *Journal* was in excellent condition financially and also in the scientific and literary material in hand. It was well known that the credit for its successful conduct was due to the editorial staff and to the Board of Editorial Advisors, but particular credit should be given to the Editor-in-Chief, who has served so many years with a reduced salary.

DR BEGG Oh, yes'

The Committee feels that, although since our final meeting there have been some suggestions made regarding changes in the By-Laws, it is impossible at a meeting of this kind to give proper consideration to some of those suggestions, and the Committee feels that it should ask that this report be adopted and these By-Laws be approved, and then if there are further changes they can be brought about through the provisions for amendments under Chapter IX, and I so move you

Dr H F R Watts, Norfolk, spoke as follows

Mr President, I am instructed by the Councilors of the Norfolk District to bring to your attention one or two phases concerning the Committee on State and National Legislation. That Committee, as everyone recognizes, has done very valiant service. It has done tremendous service under very great difficulties in that the members have done it pretty much alone. As you know, in the past it has been the great complaint, and justly so, of the Committee on State and National Legislation that when hearings occurred at the State House they could get no one to come from the Society at large to help them in those hearings. That has been a crying shame.

During the past year the Norfolk District Medical Society has established a local Committee on State and National Legislation, whose aim it has been to aid and abet the efforts of the standing Committee on State and National Legislation, and I believe not without some material help. The Council of the Norfolk District feels that better work could be done if a larger number of Fellows of the Society could be given a job in this matter and in other matters. It feels also, incidentally, that if a larger number of men are Councilors than one in thirty, there would be a greater interest in the work of the Society. More men could be put to work and given a job.

This Committee on Legislation of the Norfolk District is so organized that the day before a State House hearing, for instance, by a system of "tom-tom" spreading of information on the telephone and distribution of the work among the Fellows, a large number of the Fellows were instructed to get down to the State House the following morning at 10 o'clock, and that has been done in many instances, with some help, I believe. Therefore, the Norfolk District would like, in the interest of decentralization of the work, that this standing committee be enlarged to include one member from every District Society in the State, making 19 members—a large committee, to be sure.

The second paragraph in Section 6 of the

By-Laws, as existing and as now presented, seems to be a bit in conflict with that idea and with the endeavors of the Norfolk Committee. It says

"Any committees on state and national legislation appointed by District Societies shall be auxiliary to and under the control of this committee."

Any committee appointed by a District Medical Society must be responsible to its District Medical Society primarily, it cannot be under the control of the standing committee of the State Society. Therefore, Mr President, I am prepared, by instruction from my colleagues in the Norfolk District, to offer this change which, if the Council cannot adopt at the present time, may take perhaps the regular course of either coming up later as an amendment, as suggested, or it might very well, it seems to me, be incorporated right now in Section 6.

"The Committee on State and National Legislation shall consist of nineteen fellows, being one fellow to each District Society, together with the President, who shall be ex-officio its chairman. It shall uphold such measures" and so on.

The rest of it can stand exactly as it is now. And in lieu of the second paragraph in which it is now prescribed that committees of local District Societies shall be under the control of the standing committee, at the suggestion of my colleagues I have drafted this paragraph.

It shall encourage and foster the functioning of committees on legislative matters in each of the District Societies, to the end that District Society committees advise the Standing Committee on local conditions and requirements, that they cooperate in every way with the aims and purposes of, and through, the Standing Committee, but that they be, primarily, responsible to their local District Societies.

And the rest of the section is to remain as it is.

Dr T J O'Brien, Suffolk, a member of the Standing Committee on State and National Legislation, made an informal report of the activities of that committee, explaining what had been done by the auxiliary committees during recent time. Dr F P McCarthy, Norfolk, seconded Doctor Watts' motion. He thought that the Legislative Committee was concentrated around the City of Boston, and that it would be desirable to enlarge this committee, that the power of this committee should be spread throughout the State. Dr S B Woodward, Worcester, said that as stated by Doctor O'Brien, he had been responsible while president for the appointment of the auxiliary committees which

consist of members in each of the eighteen districts. He thought that to get together nineteen men and try to accomplish anything would not be feasible, and he thought that the present Committee on State and National Legislation was not necessarily concentrated about Boston. Certainly it had one member from Worcester.

Dr J W Bartol, Suffolk, spoke of his experience on three different committees to revise the By-Laws, the last one reporting in this very room six years ago to a day, when the By-Laws of 1928 were approved by the Council. The present committee to revise the By-Laws began its work last October, and brought in a careful revision. Many suggestions were given at the meeting last February. All Fellows had been urged to make suggestions, both by a letter in the *Journal* and by correspondence with the officers of the Society and of the District Societies. He thought that the By-Laws as presented by the Committee, with any minor changes that might be presented, ought to be approved by the Council at once, that if there were any amendments later, they could be taken care of in the customary manner by the provisions of Chapter IX of the By-Laws.

Dr C E Mongan, Middlesex South, offered an amendment as follows. On page 5 in Section 5, beginning "Councilors in number equal to one for every thirty active and retired fellows and a majority fraction thereof, as of January first, ", he would like to amend that by substituting the word "twenty" for "thirty".

Dr T H McCarthy, Plymouth, said that the Plymouth District had instructed him to move to modify the representation of Councilors from one in thirty to one in twenty-five, but he did not care to amend Doctor Mongan's motion. The amendment was seconded and put to a vote and passed. Doctor Watts' amendment was put to a voice vote and not accepted. On a rising vote it was plain that the noes prevailed by a sizable majority.

Dr J F Burnham, Essex North, spoke as follows:

Chapter VI, Section 3 the sixth paragraph of the amended By-Laws reads as follows:

"Under the direction of the Committee on Publications he (the secretary) shall issue annually, as soon as possible after the first of January, to the officers of the general Society, of the District Societies, to the Councilors, and to such other Fellows in good standing as make application at the headquarters of the Society, a directory of the officers and Fellows of the Society."

That supersedes the words "sent to the Fellows who are not in arrears." That, as you see, limits the distribution of our directory very, very much, and I think it is an error. I think the men in the trenches should be recognized

For many years we have had a directory which is the best directory of any published by any State Society in the United States and is a wonderful credit to our Secretary [Applause] It should be in the hands of every man who pays his dues.

Some of the reasons are: First, it will help a man who sends a case to another town to be able to send it to a Fellow of the Society. If a man wishes to call a consultant, he can call a consultant from that list with more certainty than he can call from a list that contains every doctor who may be in Massachusetts. It is a splendid advertisement of our Society.

We know there is some complaint among the men in the trenches that the Society is not doing much for them. We who are on the inside all know that that is not the fact. But here is one definite evidence that can be brought up that the Society has struck away one of the privileges which it has given to the practitioners throughout the State ever since the directory was published.

Doctor Begg stated that his committee had received the suggestions about the Directory and that they did not wish to see it abandoned, but were trying to save money for the Society by restricting the distribution. Doctor Burnham's motion having been seconded was passed by a unanimous vote.

The By-Laws as thus amended were approved without dissent.

The Nominating Committee having placed the following names on the blackboard and there being no further nominations from the floor, on motion duly seconded, the Councilors were requested not to vote and the Secretary to cast one ballot for the names on the blackboard:

For President William H Robey, Boston
For Vice-President Philemon E Truesdale Fall River
For Secretary Walter L Burrage Brookline
For Treasurer Charles S Butler Boston
For Orator Brace W Paddock, Pittsfield

The Secretary having cast the ballot, the President announced the above officers and orator elected.

The Council adjourned for the Cotting Luncheon at 1 10 P M.

The Council reassembled in the same room at 2 00 P M, President Robey in the chair. Dr R I Lee, Suffolk, Chairman of the Committee on Publications, presented an informal report, saying that the *Journal* was in excellent condition financially and also in the scientific and literary material in hand. It was well known that the credit for its successful conduct was due to the editorial staff and to the Board of Editorial Advisors, but particular credit should be given to the Editor-in-Chief, who has served so many years with a reduced salary.

In the absence of the Chairman, the Report of the Committee on Ethics and Discipline was read in abstract by the Secretary (See Appendix No 1) The report was accepted

Dr Reginald Fitz, Suffolk, read the Report of the Committee on Medical Education and Medical Diplomas (See Appendix No 2) The report was accepted and its recommendations adopted, including a new list of medical schools and colleges, diplomas from which are recognized by the Council, and a prize of \$50 for the best written case report by an interne

Dr Dwight O'Hara, Middlesex South, presented two reports for the Committee on Public Health (See Appendix No 3) The reports were accepted Dr T J O'Brien, Suffolk, read the report of the Committee on State and National Legislation, and it was accepted (See Appendix No 4) Dr E D Gardner, Bristol South, read the report of the Committee on Malpractice Defence and it was accepted (See Appendix No 5) Dr T J O'Brien, Suffolk, read the report of the Committee on Permanent Home, and it was accepted (See Appendix No 6) Dr W P Bowers, Worcester, stated as regards the New England Medical Council, that the New Hampshire and Rhode Island members a year ago had been disinclined to become associated with the other State Societies in meeting an equal proportion of the assessment for maintaining the work At the last meeting of the New Hampshire Medical Society there was exhibited a definite desire to have this organization kept alive, but it has seemed advisable, until there should be a more definite unanimity of opinion with reference to the functions of that Council, that the operation should be suspended until that spirit is manifested

Dr F R Ober read the report of the Committee on Postgraduate Medical Instruction It was accepted with the thanks of the Council and a vote that the Committee be continued (See Appendix No 7)

The President asked the Vice President, Doctor Truesdale, to take the Chair Dr Robey took the floor and explained the report of the Committee on Public Relations as follows

Mr Chairman, the Committee on Public Relations is now in its third year The large committee has held three meetings during the past year and the sub committee several more The small committee has had as its chairman Dr Walter A Lane The attendance at the meetings has been very large, I should say practically 100 per cent, and the men have come from all parts of the State for each meeting of our Committee

The work of the Committee has been wide in scope in the number of topics that have been considered Unfortunately, the results are small, but that is not the fault of the Committee

but simply because it has met with insuperable difficulties in the matters which it has had to handle Probably no Committee in the Society has had so difficult a piece of work to perform as has this Committee on Public Relations

I simply want to call to your attention, gentlemen, one or two points in this printed report which is in your hands First, Question 3 on page 4 (See Appendix No 8) I am just going to read that so it will be in your minds This has to do with industrial accident insurance I may say, as a preface to this, that we have had another conference this year with representatives of the claim agents and insurance companies, and, while I think they enjoy meeting with us, they are really in the same position we are Their acts are fixed by law, as are ours, but there are certain things which the Committee can do And this third question on page 4 is

"Is your staff in favor of recommending to the trustees of your hospital that any injured patient, coming under the provisions of the Workmen's Compensation Act, shall be received on a private or semi-private base charge, shall be allowed to choose from the staff a physician who shall be responsible for his treatment and care, and who shall be eligible to make reasonable charges for his services?"

There is no need of reading the list of the hospitals in the questionnaire which was sent out to a large number of them As a result of this, the Committee on Public Relations has recommended as follows (Page 4, bottom)

"We recommend that all patients who come under the provision of the Workmen's Industrial Compensation Act on admission to a hospital be referred to private or semi-private rooms and that the patient be required to choose a physician who will be responsible for his care and treatment The Secretary of the Massachusetts Medical Society shall inform by letter the trustees and staff of each hospital, admitting Industrial Accident cases to its facilities, of the action of the Council of the Massachusetts Medical Society"

DR WOODWARD I suggest substituting the word "asked" for the word "required"

PRESIDENT ROBEY Yes, substituting "asked" for "required" That was the particular advice, I think, of the Attorney-General

The next few pages have to deal with the bill introduced by the State Board of Public Health to establish a board for the examination of cases of silicosis and tuberculosis among workers That was heard by three committees, the various representatives of the State and National Legislation Committee, the Public Rela-

tions Committee, and Committees of two or three Medical Societies, as well as by the Tuberculosis Section of the Massachusetts Medical Society and the New England Roentgenological Society. The result of it all was that we convinced the three committees that no legislation was necessary because the bill had gone through the Senate and no legislation was considered necessary. It has all gone over, and Bill No 1350 now has been given up. There are two bills 1551 and 1553, which now have to do with admissions to the Department of Industry and Labor in which they admonish its members to try if possible to introduce more and more the methods of protecting the workers from dust.

There are several other matters in this report, gentlemen, but they do not need to be taken up here, or to consume time because you can read what some of the activities of the Committee have been.

I move you sir, that the report of this Committee be accepted by the Council and placed on file.

The Vice-President spoke in praise of the report, and Dr G H Bigelow, Suffolk, thought the report was disappointing. On motion by Doctor Mongan, the report was accepted and its recommendations adopted.

Dr A S Begg presented some resolutions of the Norfolk District as regards free treatment privileges in municipal and endowed charitable hospitals. (See Appendix No 9.) The resolutions were adopted by vote.

Dr H P Towle, Suffolk, spoke as follows:

When the Massachusetts Medical Society was young and the membership small, the old-time method of one program and one meeting covered every need. When, however, the membership grew larger and knowledge in medicine increased, the old method became cumbersome and inconvenient. The Section was the natural and inevitable result. The Society recognized the situation and incorporated into its By-Laws a provision for creating new Sections—Article 6, Chapter IV. To-day there are six Sections. Experience has taught that the educational value of the Section method to the general membership is immeasurably greater than that of the one program method. The papers are better prepared and, therefore, more authoritative and interesting and there is no waste of time for the members attending the Annual Meeting.

Since the dermatologists and syphilologists banded themselves together in 1915 the interest in dermatology and syphilis has increased and spread until to-day there are more than four times as many professedly interested in those subjects as there were in 1915. They feel now that the time has come when Dermatology and Syphilis should be represented at the An-

nual Meeting of the Massachusetts Medical Society by a Section of Dermatology and Syphilology for the further advancement of knowledge in these fields but particularly for the more adequate instruction of the medical public. We therefore ask your support in the establishment of such a Section under Article 6 of Chapter IV. Therefore I make the following motion:

That the Massachusetts Medical Society, here in Council assembled hereby authorizes and creates a Section of Dermatology and Syphilology, with all the rights, powers, and privileges of the other constituent Sections of the Society, to meet with the Society at the Annual Meeting of 1935 and annually thereafter.

This was discussed by Doctor Stetson of Franklin and Doctor Mongan, and the motion was passed. On nomination by Dr J H Blaisdell, Middlesex East, the following officers of the new Section were appointed: *Chairman* Dr Charles J White, Boston, *Secretary* Dr William P Boardman, Boston.

Dr W A R Chapin, Hampden, presented the following resolution of the Hampden District Medical Society:

PROPOSED RESOLUTION BY THE LEGISLATIVE COMMITTEE
OF THE HAMPDEN DISTRICT MEDICAL SOCIETY

Whereas at a meeting of the Hampden District Medical Society held in Springfield on the 4th day of April 1934, the matter of proper medical legislation in this State was discussed and

Whereas the State of Massachusetts is the only state in the Union which allows graduates of Class C schools to practice therein and

Whereas this condition draws to Massachusetts all Class C graduates who sooner or later may pass the State Board here with the result that in time Massachusetts will become a Class C state in practice if not in theory while every other state is Class A, and

Whereas for some time past all efforts made to remedy this condition have failed and

Whereas the growing complications of hospital affiliations are becoming more and more embarrassing to those institutions who would hold to established standards and force new registrants in medicine though passed by the Board as fit but who have diplomas from Class C schools, to gravitate to hospitals whose standards are lax thus encouraging low hospital standards and depriving these new men of inspirational medical contacts and proper opportunity for advancement in knowledge and

Whereas this situation affects not only the people of Massachusetts as patients but more particularly the entire medical population Doctors nurses Public Health workers and Hospitals and

Whereas a number of graduates of Massachusetts Class C schools residing in this vicinity are anxious that remedial legislation be passed forcing their schools to attain a Class A rating and

Whereas these men have signified their wish to forward the purpose of House Bill No 118 that would give the Board of Registration in Medicine the power to determine from what schools graduates would be acceptable for examination provided after such bill is passed the Massachusetts Medical Society will go on record as being willing to aid their

schools in attaining Class A rating and will not in any way oppose the attainment of this rating if the school authorities meet the requirements of Class A standards,

Now, Therefore, Be It Resolved that this society recommend to the Massachusetts Medical Society at its next convention in June, 1934, the adoption of a resolution making effective the thoughts contained herein, assuring these men of the society's cooperation

Recommended by

W. A. R. CHAPIN,
A. M. GLICKMAN,
R. R. MEUNTER,
Legislative Committee

April 24, 1934

This was discussed by Dr. J. M. Birnie, Hampden, and by invitation by Dr. E. E. W. Walker, Superintendent of the Springfield Hospital, which is a Class A hospital approved for internes by the American Medical Association. He had had difficulty in admitting as internes graduates of the Middlesex College of Medicine and Surgery, a Class C school. On motion by Doctor Birnie it was voted to refer this resolution to the following committee of five to report at the October meeting of the Council: Reginald Fitz, *Chairman*, C. H. Lawrence, Jr., C. A. Sparrow, E. S. Calderwood, and A. S. Begg.

The Chair nominated and the Council appointed the following committees for the ensuing year

STANDING COMMITTEES

COMMITTEE OF ARRANGEMENTS

W. M. Shedden, *Chairman*, W. R. Morrison,
Horatio Rogers, W. S. Burrage, R. P. Stetson

COMMITTEE OF PUBLICATIONS

R. I. Lee, *Chairman*, Homer Gage, R. B. Osgood,
R. M. Smith, F. H. Lahey

COMMITTEE OF MEMBERSHIP AND FINANCE

D. N. Blakely, *Chairman*, Gilman Osgood, G. C. Caner, J. E. Fish, H. F. Newton

COMMITTEE OF ETHICS AND DISCIPLINE

David Cheever, *Chairman*, W. D. Ruston, S. F. McKeen, A. C. Smith, R. L. DeNormandie

COMMITTEE ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS

Reginald Fitz, *Chairman*, C. H. Lawrence, C. A. Sparrow, E. S. Calderwood, A. S. Begg

COMMITTEE ON STATE AND NATIONAL LEGISLATION

W. H. Rohey, *Chairman*, T. J. O'Brien, F. E. Jones, A. W. Marsh, S. H. Wells Warren

COMMITTEE ON PUBLIC HEALTH

Dwight O'Hara, *Chairman*, E. F. Cody, F. G. Curtis, Gerald Hoeffel, G. D. Henderson

COMMITTEE ON MALPRACTICE DEFENCE

F. G. Balch, *Chairman*, E. D. Gardner, F. B. Sweet, R. P. Watkins, A. W. Allen

COMMITTEE ON PERMANENT HOME

T. J. O'Brien, *Chairman*, S. B. Woodward, O. G. Mixer, J. M. Birnie, R. B. Greenough

There being no further business it was voted to adjourn at 3 10 P. M.

WALTER L. BURRAGE,
Secretary

APPENDIX TO THE PROCEEDINGS OF THE COUNCIL

APPENDIX NO. 1

REPORT OF THE COMMITTEE ON ETHICS AND DISCIPLINE

The Committee held 8 meetings during the year (at only 1 of which was a single member absent) and conducted 7 hearings—the cases of 31 Fellows who were alleged to have violated the Code of Ethics were considered, letters of remonstrance were written to 17, one was recommended to the President for admonition, one was recommended for expulsion after joint action by the Committee on Membership and Finance and the Committee on Ethics and Discipline, under the provisions of Chapter I, Section 8, Clause (C) of the By-Laws, no one was brought before a Board of Trial. Among the alleged offenses, unethical publicity and advertising were by all odds the most numerous,—among others may be mentioned the charging of exorbitant fees, alleged commission of abortion, the giving of false and misleading testimony in Court, conspiracy to steal from insurance companies, and unprofessional conduct toward patients or other physicians.

While the above represents in broad outline the work of the Committee as a whole, it should be known that most of the essential and time-consuming work is transacted by personal interviews, conferences and correspondence with Fellows of the Society by the Chairman and Secretary, and by personal investigations of the sources and credibility of evidence by the Chairman or by some other member of the Committee. It is our impression that the help of the Committee as an arbiter of behavior and as a means of assistance for our Fellows is much more widely sought than was formerly the case. Certainly no week goes by and rarely a two or three day period without a personal or telephonic call to the Chairman for advice or for a ruling on the wisdom, good taste, or ethical character of some course of action. Many of these problems are presented by laymen who have grievances against Fellows of the Society, or who are anxious to establish schemes by which professional medical services may be "sold" to the public—of course with due pecuniary profit to the lay jobber. It is scarcely an exaggeration to say that the Committee could employ with advantage the full time of a skilled agent or investigator together with the occasional services of a lawyer, if it would aspire adequately to examine and appraise all the problems brought before it. Some of these problems may be more definitely noted.

In two instances, during the year, the Committee has taken cognizance of alleged exorbitant fees. In accordance with the policy enunciated in recent annual reports, to the effect that while our Code of Ethics wisely states that a physician, by arrangement with his patient beforehand, may attach any value he chooses to his services, nevertheless the charging of fees totally out of proportion to the value of services rendered or to the patient's means or to both, undermines the confidence of the public in our profession, tends to reduce it to the level of a trade and drives people to public clinics, cultists, or self-medication. An example of what is consid-

ered by the Committee to be an exorbitant charge, is the bill of \$4740 rendered by a Fellow to the estate of a deceased patient whom he had attended for 3½ months. The total estate was about \$12,000. The bill showed that 10 incisions of superficial abscesses under novocaine were classified as operations worth \$150 each, that 45 routine examinations of urine were considered necessary at \$8 each, that white blood counts were worth \$10, that 114 "bed side examinations" at \$10 each were differentiated from \$7 "special treatments of wounds" at \$15 each. The Committee felt that these charges could be justly characterized as raiding an estate and after a hearing voted that the Fellow be admonished by the President. Another instance was the bill for \$2590 for a not unusual rhinological operation rendered by a Fellow to a young married man unemployed whose income was \$4,000. It was shown that the patient had made a conscientious effort to find out beforehand what the operation would cost and thought that he had received assurance that it would not exceed \$1,000 which seemed to the Committee a very generous figure. In this case the Committee wrote a friendly letter to the physician expressing its conviction that he undoubtedly had a very exaggerated idea of the patient's resources and pointing out the harm that the profession might suffer from acquiring a reputation for mercenary rather than altruistic motives.

It is hoped that the Society realizes that while an investigation by our Committee may suggest, to the initiated a presumption of irregular or wrongful actions by a Fellow, the fact is that a large part of our work is concerned with the protection and exoneration of our Fellows from unfounded accusations and criticism. When a Fellow is found guilty by other authority of misdemeanors incompatible with the ethical standards of our Society we do not accept such a verdict if any doubt of its justice exists. A case which has interested us and on which we have spent much time this winter is that of a hitherto respected practitioner, a former member of this Council who is at this moment serving 2½ to 4 years in the State prison, for administering a drug with intent to cause a miscarriage. The physician and his patient emphatically assert their innocence and the evidence on which conviction was based seems dubious to the Committee. These facts together with the apparently accepted disbelief on the part of the medical profession that any drug exists which will produce miscarriage and the severity of the sentence in an age when manifest malefactors on parole or with suspended sentences go unpunished moved the Committee to make an investigation which is still going on, but in the mean time in view of the physician's conviction and sentence and the consequent revocation of his license to practice the Committee feels obliged to recommend his expulsion under Chapter I, Section 3, Clause (C) of the By-Laws.

The modern trend toward economic reorganization of medical practice and the willingness of laymen to manage our affairs for us were illustrated by schemes which were brought to our attention. A business man strongly supported by one of our Fellows allegedly representing a group of physicians proposed a plan by which he should establish an agency to secure for the employees of great corporations and their families satisfactory medical services at reasonable rates from a group of competent physicians representing the various specialties. The officers of the corporations were to advise their employees of this service and urge them to make use of it—the agent's remuneration was to be on a percentage basis of fees collected. This plan seemed to our Committee to comprise numerous un-

ethical features including a type of contract practice, the obtaining of patients by a form of advertising, the division of fees and the loss of the independent relations of physician and patient. The Committee ruled that the enrollment of Fellows of the Society in this plan would be contrary to the spirit of the Code of Ethics and to the best interests of the profession. Another business man proposed a plan along familiar lines which the Committee has disapproved on other occasions, namely, the organization of a stock company to supply under contract medical services by physicians for a fixed sum per year thus destroying the free relationship of physician and patient, obtaining patients by advertising and diverting to lay promoters a large part of the fees paid for medical service. The Committee disapproved of participation in the plan by Fellows of the Massachusetts Medical Society.

One form of abuse of medical ethics—the improper testimony of physicians in suits for malpractice has not come to the attention of the Committee during this year or indeed in recent years probably because of the efficient way in which the Committee on Malpractice Defense handles its problems. Another phase of this subject however is of considerable interest, namely whether or not our Society through the Committee on Ethics and Discipline or otherwise should take cognizance of the character of testimony offered by Fellows in courts of law especially in criminal cases. A physician reading in the daily press reports of "expert" testimony of medical witnesses brought out under the shiffling guidance of counsel for the defense can hardly fail at times to be disgusted by its partiality and by its perversion of medical learning to thwart the ends of justice. Let the intent and motive of any criticism or disciplinary action on the part of the organized profession could be similarly misconstrued and perverted so as to create serious prejudice in the minds of jury and public alike against our Society. It is a situation filled with dynamite to be handled if at all with great circumspection.

Attention has repeatedly been called in these reports to the difficulty of adjusting our traditional avoidance of anything which may savor of personal advertising to the modern craze for publicity which forces on us physicians—both willing and unwilling the attention of the newspaper and radio audience. It becomes more and more an accepted doctrine that the medical profession must "sell" itself to the public and educate the people in personal as well as in public health matters. To this end public lectures, radio broadcasts and newspaper write-ups on medical topics have become every-day occurrences. The wisdom of a good deal of this propaganda is doubted by thoughtful observers but it appears certainly desirable that the dignity of the profession should be preserved by the discouraging of personal publicity. Fellows who seek publicity under various guises in the press or on the air and who are remonstrated with can point with some justice to the example of others of the profession who under the guise of giving public instruction are brought even more effectively to public notice and can inquire as to what the difference may be. The Committee on Ethics and Discipline has long maintained that addresses on medical topics for public instruction should be signed or sponsored by a committee or officer of a medical society or school rather than by an individual or should be given by a physician not engaged in local private practice and should be on general topics rather than on the diagnosis and treatment of concrete symptoms of disease and that every effort should be made to prevent the incursion by reporters of laudatory puffs about the writer. The Committee acknowledges

with pleasure the action of three Fellows of the Society who, on having their attention called to criticism by other Fellows of offensively laudatory "write-ups" of their work, have written letters to the *New England Journal of Medicine* disavowing any responsibility therefor and supporting the efforts of the Committee to discourage such publicity.

An oft recurring question concerns the propriety of consultations with or participation in the activities of irregular practitioners of the healing art comprehended under the term "cultists." The Committee disapproves of consultations between Fellows of the Massachusetts Medical Society and cultists. A consultation implies a conference between persons holding similar views and concepts of the basic scientific principles underlying a problem. If their views are irreconcilable and fundamentally different, no true consultation can be possible. Our Code of Ethics states that "physicians should encourage sound medical learning, and uphold in the community correct views of the powers and limitations of the science and art of medicine." It seems certain that a consultation between a scientific and regularly trained physician and a cultist cannot fail to lend countenance to and dignify such a person and his cult. Naturally this expression of opinion by the Committee should not deter a Fellow from offering his help in case of emergency, at the same time letting it be known that he is not in sympathy with the cultists' creed. The Committee holds a similar view about the giving of lectures or talks by our Fellows upon medical topics, before gatherings of irregular practitioners—surely such an act cannot fail to dignify and encourage the latter.

A somewhat similar problem is presented by the giving of lectures by our Fellows to students in schools whose standards of education are so low that their diplomas are not recognized by our Council. This has been disapproved by the Committee, on the ground that such a course does not "encourage sound medical learning." In the case of a "club" composed of students and graduates of such an institution but having no official connection with it, the Committee realizing that under certain circumstances, these graduates may be eligible for Fellowship in our Society, ruled that a Fellow would not be criticized as unethical if he lectured before it, but that it considered such action unwise, especially in view of the fact that there was evidence that the giving of such lectures by our Fellows was offered as evidence of its good standing, by the authorities of the school in question.

One of the unfortunate aspects of the present economic depression is that the actual or threatened financial distress of large numbers of our profession leads inevitably to irregularities of conduct and deviations from the highest standards of practice if such relaxation seems to promise more financial return. It is much to the credit of our Fellows that in so few instances have such temptations been yielded to.

APPENDIX NO. 2

REPORT OF THE COMMITTEE ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS

During the past year this Committee has held four meetings. Two have been held for the purpose of scrutinizing the diplomas of candidates for fellow-

ship in the Society who are graduates of medical colleges unrecognized by the Council, and two for the purpose of discussing matters other than routine pertaining to problems on medical education and diplomas.

The Committee has examined by personal interview in the neighborhood of thirty candidates for fellowship in the Society. Twenty-one of these, their diplomas proving acceptable to the Committee, have passed the examinations of the Censors and have been permitted to join the Massachusetts Medical Society. During the past year, therefore, nine per cent of the new Fellows are graduates from unrecognized schools.

The Committee has meticulously studied Section 5 in Chapter VII of the revised By-Laws of the Society and believes that the description of our duties here laid down does much to strengthen the Committee's authority. We are especially impressed with the second paragraph:

"It (the Committee) shall have power to recognize a medical diploma from a foreign medical school or college or from a domestic school or college not on the list recognized by the Council, when such a diploma is presented by an applicant who has practiced for a minimum of five years, offers proof to the Committee that he is a capable and conscientious practitioner of medicine, and is recommended in confidential communications by a number of his colleagues who are Fellows of the Society. The medical diploma and written recommendations of colleagues shall be sent by the district secretary to the chairman of the Committee at least three weeks before any given examination. The Committee shall interview personally all such applicants for fellowship."

According to our interpretation of this paragraph, graduates from unrecognized medical colleges who in future wish to become Fellows of the Society must be better known than heretofore and must clearly demonstrate their capabilities not only to the examining Censors but also to the Committee on Medical Education and Medical Diplomas before they can be elected. Moreover, they must be recommended by a number of impartial Fellows through the Secretaries of the various District Societies. This proceeding should do away with the valueless type of commendatory letters which candidates have been in the habit of obtaining from uncritical friends, and should make the attainment of fellowship in the Society more difficult and therefore more valuable for candidates of uncertain medical education.

Anticipating that as soon as the revised By-Laws become effectual the Council may at once direct revision of the list of medical schools and colleges to be recognized by that body, we have completed such a revision. The Committee on Medical Education and Medical Diplomas recommends that the following list of medical schools and colleges now be recognized by the Council:

*University of Alabama School of Medicine
University of Arkansas School of Medicine
University of California Medical School
University of Southern California School of Medicine
Stanford University School of Medicine
College of Medical Evangelists
University of Colorado School of Medicine
Yale University School of Medicine
George Washington University School of Medicine
Georgetown University School of Medicine
Howard University College of Medicine
†University of Georgia School of Medicine

Emory University School of Medicine
 Rush Medical College, University of Chicago
 The School of Medicine of the Division of the Biological Sciences, University of Chicago
 Northwestern University Medical School
 University of Illinois College of Medicine
 Loyola University School of Medicine
 Indiana University School of Medicine
 State University of Iowa College of Medicine
 University of Kansas School of Medicine
 University of Louisville School of Medicine
 Tulane University of Louisiana School of Medicine
 Louisiana State University Medical Center
 University of Maryland School of Medicine and College of Physicians and Surgeons
 Johns Hopkins University School of Medicine
 Harvard University Medical School
 Boston University School of Medicine
 Tufts College Medical School
 University of Michigan Medical School
 Wayne University, College of Medicine
 University of Minnesota Medical School
 *University of Mississippi School of Medicine
 Washington University School of Medicine
 *University of Missouri School of Medicine
 St. Louis University School of Medicine
 University of Nebraska College of Medicine
 Creighton University School of Medicine
 *Dartmouth Medical School
 Columbia University College of Physicians and Surgeons
 Albany Medical College
 University of Buffalo School of Medicine
 Long Island College of Medicine
 New York Homeopathic Medical College and Flower Hospital
 Syracuse University College of Medicine
 New York University University and Bellevue Hospital Medical College
 Cornell University Medical College
 University of Rochester School of Medicine
 *University of North Carolina School of Medicine
 *Wake Forest College School of Medicine
 Duke University School of Medicine
 *University of North Dakota School of Medicine
 Western Reserve University School of Medicine
 Ohio State University College of Medicine
 University of Cincinnati College of Medicine
 University of Oklahoma School of Medicine
 University of Oregon Medical School
 University of Pennsylvania School of Medicine
 Jefferson Medical College
 Woman's Medical College of Pennsylvania
 Hahnemann Medical College
 University of Pittsburgh School of Medicine
 Temple University School of Medicine
 Medical College of the State of South Carolina
 *University of South Dakota School of Medicine
 Vanderbilt University School of Medicine
 University of Tennessee College of Medicine
 Meharry Medical College
 University of Texas School of Medicine
 Baylor University College of Medicine
 *University of Utah School of Medicine
 University of Vermont College of Medicine
 University of Virginia Department of Medicine
 Medical College of Virginia
 *West Virginia University School of Medicine
 University of Wisconsin Medical School
 Marquette University School of Medicine
 University of Alberta Faculty of Medicine
 University of Manitoba Faculty of Medicine
 Dalhousie University Faculty of Medicine
 University of Toronto Faculty of Medicine
 Queen's University Faculty of Medicine
 University of Western Ontario Medical School
 McGill University Faculty of Medicine

University of Montreal Faculty of Medicine
 Laval University Faculty of Medicine
 *University of Saskatchewan School of Medical Sciences

These schools offer only first two years of medical course no longer awarding medical diplomas

†Only diplomas previous to 1934 are to be recognized

Two members of the Committee attended the meeting of the Association of American Medical Colleges held in Rochester, Minnesota last fall, and the Congress on Medical Education, Licensure and Hospitals of the American Medical Association held in Chicago in February. The Committee continues to consider it an important duty for its members to attend such meetings as regularly as possible, not only to be able to inform Fellows at home regarding any interesting new developments that may come forth at such gatherings, but also so that our experience on matters dealing with Medical Education and Medical Diplomas may be of help to other State Medical Societies throughout the country.

The Committee regards with great pride the progressive and public spirited attitude assumed by the Society in questions pertaining to medical education. We feel that the experiment in postgraduate instruction carried out by the Society during the past year has been notably successful and is an undertaking worth carrying forward. The Committee on Medical Education and Medical Diplomas by virtue of having two members on the Committee on Postgraduate Medical Instruction has been in active liaison with the latter Committee during the entire year and continues eager to do all in its power to establish in Massachusetts a well-organized method by which the Society shall offer its Fellows continuously improving opportunities to keep up with the increasing ramifications of medical knowledge.

We believe that there is one important aspect of postgraduate instruction in Massachusetts so far unconsidered which deserves study. This deals with the training of interns. We have made a preliminary survey of Massachusetts internships and already have reported the results of the survey to the Council. We ask for authority to study further the internships available to young doctors in Massachusetts having in mind inspection of all hospitals in the state which wish to go on record as being properly qualified to offer intern training. We believe that it would be very advantageous to medical students if the internships available in Massachusetts could be formally classified and described by the Society and that systematic inspection from time to time would be advantageous to the various hospitals.

Finally we advocate that the Society be moved to offer an annual prize of \$50 for the best written and most comprehensive case report submitted by interns holding any of the rotating internships now offered in Massachusetts and approved by the American Medical Association. Such a prize would do much to stimulate medical writing among younger men and would help to disseminate throughout the State the importance and interest of keeping abreast of medical literature. The prize each year might be awarded by an editorial committee appointed by the President including himself or his representative a member of the Committee on Publications, a member of the Committee on Medical Education and Medical Diplomas a member of the Editorial Board of the *New England Journal of Medicine* and a member representing the President of the Boston Medical Library.

APPENDIX NO. 3

REPORT OF THE COMMITTEE ON PUBLIC HEALTH

During the past year the Committee on Public Health has been studying the periodic health examination. The Division of Adult Hygiene of the State Department of Health precipitated this study by asking the Committee to cooperate in an educational campaign intended to popularize health examinations in this State.

The Committee published a communication on the subject in the January 25 issue of the *New England Journal of Medicine*. This communication was based upon the invited opinions of members of the Council, and was drafted with the cooperation of the State Department of Public Health. A recent poll of the members of this Council reveals that the communication as printed was satisfactory to 90 per cent of the members replying. In so far as the Council represents the Fellows of the Society, then, the Committee feels that for the present this communication can be accepted as it stands.

On the other hand, the Public Health Council has advised the State Department of Public Health that "The desirability of periodic health examinations annually versus a physical examination to clear up indefinite or minor ailments or symptoms was discussed at length and it was the consensus of opinion of the medical members of the Council that the annual periodic health examination formerly advocated by the Department is still desirable and the Department should continue to recommend it when ever the opinion of the Department is requested." This leaves the State Department in a somewhat awkward position.

In the *American Medical Association Bulletin* for March of this year there is a paper on the subject by Dr. Bauer, who concludes as follows: "The periodic health examination seems to be at this time, in a status which all movements reach sooner or later. The initial stage of enthusiasm for a new idea has been passed. A lull has come. Physicians are doubting, considering, questioning. It is a wholesome indication. If the conception of regular health examinations at intervals is sound it will emerge from this phase and be carried forward, if it is unsound, it will die."

DWIGHT O'HARA, *Chairman*,
E. F. CODY
F. G. CURTIS,
G. N. HOFFEL,
G. D. HENDERSON.

REPORT OF COMMITTEE ON PUBLIC EDUCATION

This Committee has continued to cooperate with the State Department of Public Health in the joint sponsorship of weekly broadcasts of a popular variety on medical topics. A recent survey by the Division of Adult Hygiene indicated that there are approximately forty thousand people listening to these broadcasts each week. Other groups than ours have broadcast similar series—in some cases quite as good as our own. When this was the case we could only be pleased that the work was so well done.

The Harvard Medical School has continued its public lectures with their associated newspaper publicity, sometimes of a highly personal nature. Probably anyone who toys with "the Devil's of the press" will find, as Osler said, that "sooner or later she is sure to play the harlot."

The rivalry between the broadcasting companies and the newspapers which has been referred to in

our previous reports has during the past few months been developed to the point where the broadcasting companies are now gathering their own news items instead of depending upon the newspapers for this material as heretofore. The time when we might use the same copy for both radio and newspaper publicity has therefore probably passed.

The Committee has no desire to expand its activities to include the newspapers, but it is interested in the effectiveness of any method used to influence the public. Some of its members question the worth of any of these methods. The profession is now dipping its toes in the waters of publicity. Some day it must decide whether it is going to go in all over or go back and put on its clothes.

The Committee has referred in previous reports to the "better health" theme which has woven itself into the radio programs of the commercial purveyors. Within the past few days we have been asked to present the resolutions concerning those abuses to the Society. This we plan to do at the annual meeting of the Society tomorrow.

DWIGHT O'HARA, *Chairman*

APPENDIX NO. 4

REPORT OF THE COMMITTEE ON STATE AND NATIONAL LEGISLATION

After the Annual Meeting of 1933, an educational campaign was planned and the Chairman with a member of the committee, visited sixteen cities throughout the State in the summer and fall of that year and six cities in 1934. District medical societies, hospital staffs and medical groups were addressed and methods of organization were specified. It outlined the value of personal contact with influential citizens and especially with local legislators was emphasized. The aid of allied professions, as the State organizations of dentistry, pharmacy and nursing was obtained for our mutual advantage.

When the Legislature convened in January 1934, the various bills were studied and a definite action was decided upon each one. Forty-six bills were introduced which would have influenced the teaching of medicine or the practice of the healing art in this State. Members of our committee attended fourteen hearings during the present session.

Our present economic problems have caused the average physician to become 'politically minded'. We refer particularly to the physician with a small equity in a home with children at college or with heavy overhead expenses. We kept in close contact with federal and civic bills drawn to influence compensation or payment to physicians for welfare service.

The interest taken by physicians was state-wide and every local legislative committee is worthy of honorable mention for its active cooperation. Our method of having groups of physicians accompanied by influential citizens of a community present the principles involved in each important bill to their Legislators has been most satisfactory and we advise the continuance of this plan. Our By-Laws state that the Committee on State and National Legislation "shall oppose such measures as it may deem contrary to the public welfare and support and initiate measures which promise to advance a higher standard of medicine and promote the public welfare. We therefore recommend that no bills be introduced by members of the Massachusetts Medical Society unless said bills have been submitted to your committee for approval or disapproval. A member may introduce a petition as an individual but it is unwise to permit him to state the position of

our Society at a hearing or elsewhere when neither the Council nor the Committee on State and National Legislation has given him authority to do so

In brief our report is comparable to that of other years. We did not succeed in having any constructive legislation passed but we have been able to prevent the passage of bills which would have lowered the present standard of practicing the healing art in Massachusetts

THOMAS J O'BRIEN
FREDERICK E JONES
ARTHUR W MARSH
SHIELDS WARREN

APPENDIX NO 5

REPORT OF THE COMMITTEE ON MALPRACTICE DEFENCE

This Committee has been impressed by the fact that there has not been an increase in the number of cases brought to its attention during the past year as was expected due to the financial condition of the times

There have been only two new cases during the period from May 11 1933 to May 13 1934. There were ten cases pending up to May 11 1933. One of these cases has been disposed of leaving eleven cases pending at the present time. The case that was disposed of during the past year was one that was dismissed for lack of prosecution under the rule just as it was about to be reached for trial.

The Committee has not been informed of any unfair testimony in Court by any members of the Society during the past year.

FRANKLIN G BALCH *Chairman*
EDWIN D GARDNER
FREDERICK B SWEET
ROYAL P WATKINS
ARTHUR W ALLEN *Secretary*

APPENDIX NO 6

REPORT OF THE COMMITTEE ON PERMANENT HOME

Our present plan of paying a proportionate rate of maintenance to the Boston Medical Library continues until September 30 1936. The headquarters are being used much more frequently by members and by committees and the service rendered by the clerical force of the *New England Journal of Medicine* has been most satisfactory.

Your committee carefully considered the offer of a realtor concerning a certain estate on Beacon Street, Boston. While the price was satisfactory the location of the property and the interior arrangement were not suitable for our needs as a permanent home. We voted unanimously not to accept it.

Our Building Fund has a book value of \$52 679 and we hope to increase this total by future bequests and contributions.

ROBERT B GREENOUGH

APPENDIX NO 7

REPORT OF THE COMMITTEE ON POSTGRADUATE MEDICAL INSTRUCTION

The Committee on Postgraduate Instruction wishes to submit its first annual report. The pro-

gram was begun a little over a year ago the first course was started in Plymouth District on October 9 1933 the last course to finish was Bristol North District on May 15, 1934. During this first teaching year all districts of the Society appointed chairmen on postgraduate instruction; without exception they have all functioned well. Much credit for the success of the courses is due to the unstinted interest and labor of these district chairmen.

In all two hundred and thirty-two sessions were held in the various districts. These covered eighteen subjects. A faculty of one hundred and seventy instructors was organized they went in teams of two or three. This method of teaching has been much appreciated by those who took the courses. Much credit and praise are due this group of devoted teachers who have given so generously of their time and effort to render a service which will have a lasting value to the Fellows of the Massachusetts Medical Society.

Although the Massachusetts Medical Society is not the first to start this type of extension teaching, our methods have attracted widespread interest. Already other state societies have written to the committee for information in regard to the plan of postgraduate instruction as sponsored by this Society.

On February 7 1934 the district chairmen on postgraduate instruction held a meeting in Boston and voted unanimously to ask that the Council authorize the continuation of this work next year. At the present time the committee is preparing a new program which will be presented for the consideration of the Society in the near future.

A statistical summary of the past year's work follows:

Total number of postgraduate courses offered	22
Total number of postgraduate courses chosen	18
Total number of sessions	232
Number of district societies cooperating (100%)	18
Number of places where courses were given	24
Total registration for all courses	1002
Largest registration for one course	110
Smallest registration for one course	10
Total faculty	170

The Committee wishes to thank all officers and Fellows of the Society who have contributed to the success of this work. The Committee considers that the project of giving extension postgraduate instruction is very much worth while and recommends that a committee be appointed to arrange the program for the coming year.

APPENDIX NO 8

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

I. Relative to hospital Plans A and B as designed for some nineteen hospitals in Metropolitan Boston, the Massachusetts Medical District Societies of Suffolk Middlesex South and East and Norfolk have in substance voted adversely to the acceptance of either plan. It may be that some time in the future adequate discussion between the hospital executives and a representative Medical Commission formed by the Committee on Public Relations may result in a mutually satisfactory plan as it is obvious that neither can exist and serve to the best advantage its several communities without the close cooperation of both parties.

APPENDIX NO 3

REPORT OF THE COMMITTEE ON PUBLIC HEALTH

During the past year the Committee on Public Health has been studying the periodic health examination. The Division of Adult Hygiene of the State Department of Health precipitated this study by asking the Committee to cooperate in an educational campaign intended to popularize health examinations in this State.

The Committee published a communication on the subject in the January 25 issue of the *New England Journal of Medicine*. This communication was based upon the invited opinions of members of the Council, and was drafted with the cooperation of the State Department of Public Health. A recent poll of the members of this Council reveals that the communication as printed was satisfactory to 90 per cent of the members replying. In so far as the Council represents the Fellows of the Society, then, the Committee feels that for the present this communication can be accepted as it stands.

On the other hand, the Public Health Council has advised the State Department of Public Health that "The desirability of periodic health examinations annually versus a physical examination to clear up indefinite or minor ailments or symptoms was discussed at length and it was the consensus of opinion of the medical members of the Council that the annual periodic health examination formerly advocated by the Department is still desirable and the Department should continue to recommend it when ever the opinion of the Department is requested." This leaves the State Department in a somewhat awkward position.

In the *American Medical Association Bulletin* for March of this year there is a paper on the subject by Dr. Bauer who concludes as follows: "The periodic health examination seems to be at this time, in a status which all movements reach sooner or later. The initial stage of enthusiasm for a new idea has been passed. A lull has come. Physicians are doubting, considering, questioning. It is a wholesome indication. If the conception of regular health examinations at intervals is sound it will emerge from this phase and be carried forward. If it is unsound, it will die."

G. D. HENDERSON.

REPORT OF COMMITTEE ON PUBLIC EDUCATION

This Committee has continued to cooperate with the State Department of Public Health in the joint sponsorship of weekly broadcasts of a popular variety on medical topics. A recent survey by the Division of Adult Hygiene indicated that there are approximately forty thousand people listening to these broadcasts each week. Other groups than ours have broadcast similar series—in some cases quite as good as our own. When this was the case we could only be pleased that the work was so well done.

The Harvard Medical School has continued its public lectures with their associated newspaper publicity sometimes of a highly personal nature. Probably anyone who toys with "the Delliiah of the press" will find, as Osler said that "sooner or later she is sure to play the harlot."

The rivalry between the broadcasting companies and the newspapers which has been referred to in

our previous reports has during the past few months been developed to the point where the broadcasting companies are now gathering their own news items, instead of depending upon the newspapers for this material as heretofore. The time when we might use the same copy for both radio and newspaper publicity has therefore probably passed.

The Committee has no desire to expand its activities to include the newspapers but it is interested in the effectiveness of any method used to influence the public. Some of its members question the worth of any of these methods. The profession is now dipping its toes in the waters of publicity. Some day it must decide whether it is going to go in all over or go back and put on its clothes.

The Committee has referred in previous reports to the "better health" theme which has woven itself into the radio programs of the commercial purveyors. Within the past few days we have been asked to present the resolutions concerning those abuses to the Society. This we plan to do at the annual meeting of the Society tomorrow.

DWIGHT O'HARA, *Chairman*

APPENDIX NO 4

REPORT OF THE COMMITTEE ON STATE AND NATIONAL LEGISLATION

After the Annual Meeting of 1933 an educational campaign was planned and the Chairman with a member of the committee, visited sixteen cities throughout the State in the summer and fall of that year and six cities in 1934. District medical societies, hospital staffs and medical groups were addressed and methods of organization were specifically outlined. The value of personal contact with influential citizens and especially with local legislators was emphasized. The aid of allied professions, as the State organizations of dentistry, pharmacy and nursing was obtained for our mutual advantage.

When the Legislature convened in January, 1934 the various bills were studied and a definite action was decided upon each one. Forty-six bills were introduced which would have influenced the teaching of medicine or the practice of the healing art in this State. Members of our committee attended fourteen hearings during the present session.

Our present economic problems have caused the average physician to become 'politically minded'. We refer particularly to the physician with a small equity in a home with children at college or with heavy overhead expenses. We kept in close contact with federal and civic hills drawn to influence compensation or payment to physicians for welfare service.

The interest taken by physicians was state-wide and every local legislative committee is worthy of honorable mention for its active cooperation. Our method of having groups of physicians accompanied by influential citizens of a community present the principles involved in each important bill to their Legislators has been most satisfactory and we advise the continuance of this plan. Our By-Laws state that the Committee on State and National Legislation "shall oppose such measures as it may deem contrary to the public welfare and support and initiate measures which promise to advance a higher standard of medicine and promote the public welfare." We therefore recommend that no bills be introduced by members of the Massachusetts Medical Society unless said bills have been submitted to our committee for approval or disapproval. A member may introduce a petition as an individual but it is unwise to permit him to state the position of

an industrial case there in the semi private rooms?

	Yes	No	Ans
Hospitals in Boston	4	4	2
Hospitals outside Boston	26	8	50

We recommend that all patients who come under the provision of the Workmen's Industrial Compensation Act on admission to a hospital be referred to private or semi private rooms and that the patient be required to choose a physician who will be responsible for his care and treatment. The Secretary of the Massachusetts Medical Society shall inform by letter the trustees and staff of each hospital, admitting Industrial Accident cases to its facilities, of the action of the Council of the Massachusetts Medical Society.

III. In July, 1933 there was appointed by the Governor a board of five to inquire into the aspects of certain industrial diseases, e.g., silicosis and allied diseases in relation to tuberculosis. The Public Relations Committee was vitally interested in this matter because of the intention of the Legislative Act to enlarge the functions of the State Department of Health in establishing and training a personnel of diagnosticians, as an integral part of the Department of Health, who would examine and recommend the disposition of some 8650 men in industry, the number to be examined probably increasing as other fields were opened up. The Act provided in part as follows

Section 5 Entrance Physical Examinations

That legislation be enacted to provide (a) that no person not previously so employed in the Commonwealth shall engage in any occupation in the granite or foundry industry in which there may be harmful exposure to dust unless his physical fitness so to do has been determined, within the twelve months next preceding, by the Department of Public Health by means of an examination, (b) that any person not prohibited by statute or regulation thereunder from engaging in such occupation and who has not been so examined within the twelve months next preceding shall be given opportunity to be so examined within thirty days after filing with the department a written application including a signed statement that it is his purpose to engage in such an occupation, (c) that the examinee shall be notified in writing, within ten days after such examination, whether or not he is found physically fit to engage in such an occupation (d) that if an examinee found unfit files with the department within ten days after such notification a written appeal from the finding, it shall be reviewed by the Medical Board of Review provided for in the following recommendation numbered fourteen, which board shall hold a hearing if requested by the examinee and shall render to the department a decision which shall be final and of which notice shall be sent to the examinee as hereinbefore provided, (e) that no member or employee of the department or of the board, nor any of their records shall be subject to subpoena in connection with the case of any person so examined, nor shall any such records be made public except at a hearing as hereinbefore provided, (f) that there shall be issued to each examinee found physically fit to engage in such occupation a certificate of fitness which shall bear the signature of the examinee and the date of the examination and shall be duly executed under the direction of the commissioner of public health and (g) that no further examination of the lungs shall

be necessary as a condition precedent to such employment of a person to whom a certificate of fitness has been issued within the twelve months next preceding

Section 6 Annual Physical Examinations

That legislation be enacted to provide (a) that every person engaged in any occupation in the granite or foundry industry in which there may be harmful exposure to dust shall annually be examined by the Department of Public Health to determine his physical fitness to continue in any such occupation (b) that no finding of such physical unfitness shall be made except on evidence of active pulmonary tuberculosis, (c) that every examinee found unfit so to continue shall be so notified in writing, (d) that if an examinee found unfit files with the above department within ten days after such notification a written appeal from the finding, it shall be reviewed by the Medical Board of Review provided for in the following recommendation numbered fourteen which board shall hold a hearing if requested by the examinee and shall render to the above department a decision which shall be final, (e) that, if the decision is contrary to the finding reviewed the examinee shall be so notified in writing, (f) that, if the decision confirms the finding reviewed, or if an examinee found unfit fails to appeal as hereinabove provided, the Department of Public Health shall in writing notify the Department of Industrial Accidents and the Department of Labor and Industries that the examinee has been found physically unfit to continue in any occupation as hereinbefore described and the last named department shall so notify the examinee and his employer, if any (g) that an examinee so found unfit may apply, not less than twelve months after such finding, for a reexamination in accordance with provisions (b), (c), (d), (e) and (f) of the recommendation next preceding any certificate of fitness issued in such case to bear the word "readmitted", (h) that any person who, having received notice of physical unfitness from the Department of Labor and Industries as hereinbefore provided, continues in any occupation for more than thirty days in contravention thereto or returns to such occupation except after readmission as hereinbefore provided shall forfeit all rights to compensation for disability due to pulmonary disease under the Workmen's Compensation Act, (i) that no member or employee of the Department of Public Health or of the Medical Board of Review, nor any of their records shall be subject to subpoena in connection with the case of any person examined as hereinbefore provided nor shall any such records be made public except at a hearing as hereinbefore provided, (j) that the Division of Tuberculosis of the Department of Public Health shall give special preference in the extension of its facilities to persons who, deprived of employment because of a finding of unfitness as hereinbefore provided, have been resident in the Commonwealth on the effective date of this legislation or for one year prior to the date of such finding, (k) that the Division of Public Employment Offices of the Department of Labor and Industries shall give special preference in the extension of its facilities to the dependents of such persons, (l) that the Division of Public Employment Offices of the Department of Labor and Industries and the Division of Rehabilitation of the Department of Education shall give special preference in the extension of their facilities to such persons if subsequently restored to fitness for employment, (m) that every person who having been deprived

II On December 27, 1933 the Public Relations Committee met with the Secretary of the Claims Executive Committee of the Casualty Insurance Companies relative to the proposals made last May as presented to and approved by the Council of the Massachusetts Medical Society in June. He explained that the insurance companies could not take on added industrial expense as might be entailed by our recommendation No 1, relative to admitting patients to hospitals as private patients—as they could not estimate the expense and they did not think anyone had figures that would be reliable. Furthermore he said that no one except the staff doctors would benefit. Finally it was unacceptable and the insurance companies preferred to carry on, as heretofore without payment to the doctors for individual accident cases admitted to the wards for hospitalization. No 2 in re consultations, the insurance companies made no objection and continued to indorse the proposition. No 3 relative to the fairness of our charges—requires no comment. No 4 concerns two weeks' treatment and the record sheet. The insurance companies are getting out a new uniform record sheet which they propose to use as a unit. No suggestion was offered for distribution or the availability of these in blank, and no proposal was made to alter the "present two weeks treatment except in exceptional cases." No 5 has to do with the recommendation of a board of three medical men to advise the Industrial Accident Board as to their findings in disputed cases. Here the insurance companies took no action—they would not support it, and neither would they contest it. They "leaned away from the recommendation, but would go along with the Board." No 6—the Insurance Companies contend that the rules of evidence do not allow of an affidavit of the individual's physical condition and they therefore are antagonistic to the recommendation.

The end result of our conference was that, contrary to the opinion given to us, the insurance companies prefer to operate along legalistic lines rather than the cooperative methods outlined.

Meanwhile the Public Relations Subcommittee learned that in several communities industrial accident cases were automatically admitted to the hospitals as private or semi private cases, as the individual was required to choose a physician for his care, signing a paper so indicating and then two witnesses affixing their signatures, so that the following letter and questionnaire were sent out to various hospitals throughout the State

HOSPITALIZATION OF WORKMEN'S COMPENSATION CASES

The following recommendation of this committee was endorsed in June, 1933, at a meeting of the Council of the Massachusetts Medical Society

"As the employers have paid premiums for the care of the working man's injuries it is unreasonable to expect that doctors inside or outside of hospitals should take care of those cases without pay. We should ask that a patient sufficiently injured to need hospitalization should be recommended to a hospital as a *private patient*. We affirm that nurses and other agents should act only under the authority of the physician in charge of the case. Both the insurance companies and the doctors should be primarily interested in the early return of that patient to his work with as good a functional result as could be obtained. We believe that that principle is better business both for the

insurance companies and the injured party, the hospitals and the attending doctor."

Your committee was aware that a number of hospitals in the state are now admitting industrial cases only to the semi private rooms, thus allowing the attending physician to charge for his services. In order to find out how general this practice is, the following questionnaire was sent out to one hundred and twenty hospitals outside the city of Boston. Essentially the same inquiry was made by the Norfolk District Medical Society to twenty hospitals within Boston limits. Some hospitals particularly in the Boston group, because of the nature of their work, have no occasion to admit industrial cases. Eighty per cent of the balance in both groups admitting industrial cases have returned the questionnaire, and the tabulated results are as follows—

- 1) In your hospital, are industrial cases admitted as ward patients, in which case the attending physician receives no compensation?

Yes No No Ans

Hospitals in Boston 6 1 1

Hospitals outside Boston 13 71 0

Two hospitals in the Boston group answered "Yes and No." Seven out of the thirteen hospitals outside Boston answering "Yes" were located in Boston suburbs.

- 2) In your hospital, are industrial cases admitted only as private patients to the semi private rooms, in which case the attending physician does receive compensation?

Yes No No Ans

Hospitals in Boston 4 4 2

Hospitals outside Boston 71 13 0

Eighteen out of the seventy-one hospitals outside Boston answering "Yes" admit industrial cases to the wards as private ward cases. Six of these eighteen are located in Boston suburbs.

- 3) Is your staff in favor of recommending to the trustees of your hospital that any injured patient, coming under the provisions of the Workmen's Compensation Act shall be received on a private or semi private base charge, shall be allowed to choose from the staff a physician who shall be responsible for his treatment and care, and who shall be eligible to make reasonable charges for his services?

Yes No No Ans

Hospitals in Boston 8 0 2

Hospitals outside Boston 69 2 13

- 4) Does your hospital have a "closed" staff?

Yes No No Ans

Hospitals in Boston 8 2 0

Hospitals outside Boston 40 41 3

- 5) Does your hospital have a "courtesy staff" which enables any reputable physician to treat industrial cases in the semi private rooms?

Yes No No Ans.

Hospitals in Boston 5 5 0

Hospitals outside Boston 67 16 1

- 6) If tightly "closed", would, in your opinion, your staff be willing to open its doors through a "courtesy staff" to any reputable physician who might desire to treat

"Whereas, this procedure is antagonistic to the Massachusetts Law for workmen's compensation in so far as it deprives the injured workman of the right to select his own physician,

Be it resolved that the Massachusetts Medical Society, composed of four thousand and nine hundred Massachusetts physicians, acting through the Committee on Public Relations protests the application of the Federal Compensation Act to the Civil Works program in Massachusetts and

Be it further resolved that we respect fully urge that the man injured in Civil Works program has the right to select his own physician'

In answer to this, we have under date of January 15 the following reply

"FEDERAL CIVIL WORKS ADMINISTRATION,
1734 NEW YORK AVENUE, WASHINGTON

January 15, 1934

'Thank you for sending us copy of telegram from the Massachusetts Medical Society

The United States Employees Compensation Commission is administering the compensation provisions for Civil Works Administration employees. However, the Commission has informed our State Administrators that the bulletin on medical facilities which shows the physicians designated to treat injuries, is of long standing and was not issued for Civil Works purposes but for the treatment of Civil employees of the United States that for Civil Works purposes it was not intended to exclude other reputable physicians willing to give treatment at reasonable rates in accordance with Rules and Regulations No 5 and that local administrators are authorized to advise the local medical profession and organizations accordingly and to make arrangements to permit such physicians to participate in rendering this service on the basis indicated

Very truly yours

BRUCE MCCLURE, Secretary
Federal Civil Works Administration

However, we are informed by the President of the Massachusetts Medical Society that he is unable to find at the present time, January to June that any funds are available for the payment to physicians in civil practice who may have been called to attend such cases

The following recommendation was adopted by the Council at its meeting in February 1934 and is inserted here as a matter of record

The Committee recommends that it be authorized by the Council to represent the Society's interests in dealing with Federal Emergency Relief Administration Civil Works Administration and such other economic measures as may from time to time arise. We further recommend that a committee be established by each district society to act as liaison with local governmental officials and through the Public Relations Committee of the State Society with the State administration. This will establish machinery in Massachusetts in accordance with federal recommendations in Bulletin 7 F. E. R. A. and as is well exemplified by the New Jersey State and local societies (reported in the *A. M. A. Bulletin* for October)

Free exchange between local and state committees of information on policies and actions is highly desirable

VII

COSTS OF MEDICAL CARE

Since the publication of the report on the Costs of Medical Care, there has been so drastic a change in economic conditions that many of the factors upon which the Committee based its findings are not applicable today. Interest has been aroused both within and without the medical profession, however, and we recommend that doctors in their several communities forward a movement for the more efficient control of disability and disease. The problem will vary in the different parts of the State and probably in different cities and may be met in part by the following suggestions

1) Availability of hospital beds for the use of the practitioner not on the visiting staff of the hospital (Tends to education and better standing of the local practitioner with consequent better care of his patients) It is probable that in teaching hospitals there would be less possibility of this procedure than in institutions not primarily devoted to teaching

2) Group practice, e.g., Hanover, New Hampshire plan (May be varied according to local conditions)

3) Closer coöperation of the local and State Boards of Health with the medical profession. In any health measure the local doctors are as much interested as anyone, probably more so. This is also highly applicable to the State Board of Health tuberculosis program

4) Rigid scrutiny of the patient applying for free treatment at a hospital (The efficient care of the indigent sick in the communities obviates the menace of State Medicine) Statistics seem to indicate that from one to seven per cent abuse the privilege of hospitals for the care of indigent patients and it may be that because of our refinements in medical practice obtainable at the hospitals in contradistinction to general practice that this demand is made by both the poor and the well-to-do. Bearing on this are certain resolutions to be introduced on the floor by the Norfolk District Medical Society which we heartily endorse in principle and commend to the favorable consideration of every Councilor present.

5) Adequate representation of Doctors of Medicine on hospital boards. In no other profession is it apparent that their activities are so largely directed by extraneous even though perhaps sympathetic agencies

6) Entrance of the doctor into public life. With his educational and social background greater opportunities for the people he represents await his willingness to take this step. Medical practice is undergoing a process of evolution and if we can do so without entering upon a period of dangerous experimentation either upon ourselves or our patients it behooves us to meet changing conditions with changing methods learning what to avoid by the unfortunate English panel and German governmental systems and by contact with other sections of the Country inaugurate those principles proved to be acceptable and successful

In all of the above suggestions much might be said in elaboration of the ideas which we believe may be left to the imagination of those interested but more

of employment because of a finding of unfitness as hereinbefore provided and being in need of relief or assistance, has been a citizen of the Commonwealth on the effective date of this legislation or for one year prior to the date of such finding shall, on having received compensation for disability due to pulmonary disease in the full statutory amount, or at once if ineligible for such compensation, be entitled to assistance as provided for by Chapter 118A of the General Laws, as amended, irrespective of any provision thereof contrary hereto, for as long as such need and unfitness continue, and (n) that the official or body providing such assistance may at any time require that any such person be reexamined, as hereinbefore provided, in order to determine whether or not the unfitness continues

Section 13 Occupational Medical Staff

That legislation be enacted to provide that there be added to the personnel of the Division of Adult Hygiene of the Department of Public Health a medical staff and such assistants and facilities as may be necessary to the efficient performance of their duties, which shall be (a) to investigate and report to the Industrial Accident Board on the medical aspects of all cases coming before the board for compensation for silicosis, asbestosis or pulmonary tuberculosis and to so investigate and report in such cases coming before the board for other occupational diseases as the board may refer to them, their reports and findings to be admissible as evidence before the board or any member thereof, but no member or employee of the department to be subject to subpoena in connection therewith, (b) in any fatal case coming before them, to order an autopsy if in their opinion it is advisable for the purpose of determining a fact material to any party at interest, (c) to make such findings of physical fitness as are provided for in the preceding recommendations numbered five and six, (d) to study the effects upon health of materials and processes used in industry, in connection with which studies no member or employee of the department shall be subject to subpoena, and (e) in cooperation with the Department of Labor and Industries, to promote occupational health education.

The question was brought before the New England Roentgen Ray Society and the Tuberculosis Section of the Massachusetts Medical Society. The following resolution relative to the matter was passed by the New England Roentgen Ray Society

March 16, 1934

Be it resolved that the New England Roentgen Ray Society in meeting assembled by a unanimous vote strongly disapproves of Sections five, six and thirteen of the recommendations of the State Department of Public Health for legislation regarding the appointment of a special Industrial Disease Commission for the following reasons

1 That although yearly examinations of employees in industry may be desirable, it is not within the province of the Department of Public Health to spend funds for the protection of private injury

2 That the present provisions of the Workmen's Compensation Act for the employment of impartial physicians make such legislation unnecessary

3 That the proposed plan of placing the study of these cases in the hands of men inexperienced in roentgenology and equipped

with inadequate apparatus is unsound, especially when there are men of broad experience with adequate apparatus available

A committee appointed by the President of the Massachusetts Medical Society was unanimous in condemning the section of the Act designed to allow the establishment of this clinical board though wholly sympathetic with the ideas of preventive medicine incorporated in the bill. We hope that if further revision of the bill seems advisable, that adequate representatives of the Massachusetts Medical Society may be added to the board as originally appointed, believing that less drastic measures, educational to industry, may lead to the desired result.

We recommend that the Massachusetts Medical Society through its President actively concern itself in medical appointments and activities outside of legislative matters at the State House

IV A meeting was held in April of the Public Relations Subcommittee with two members of the Public Health Council and the Commissioner of Public Health which was largely devoted to a discussion of present and future policies of the State Department of Health. Insistent and cordial encouragement was given to the Commissioner to call upon the Massachusetts Medical Society through its President for discussion and cooperation of its program as it develops, dependent on the state of public health. We had been disturbed by newspaper reports and other sources of information of proposed enlargement of the State functions relating to the care of Chronic Heart Disease and Arthritis. We are definitely assured that the Department of Public Health does not wish for such added burdens and that the Cancer Control program was enacted by legislation contrary to its desires. We are deeply appreciative of the excellence of the work done under the direction of the State in its Cancer program but we believe that this should have been inaugurated by the Massachusetts Medical Society and future programs for the alleviation and care of chronic diseases should be initiated and controlled through agencies of the Massachusetts Medical Society.

We deprecate the attitude of certain interests that, without forwarding specific education of the medical profession in so far as the present understanding of the disease process permits, are already agitating for state hospitalization and care of individuals so afflicted with arthritis as to need medical attention. We urge the medical profession's organized opposition to any plan that would provide facilities for terminal hospitalization in such cases. Such a program presumes that medical knowledge is static and would enormously increase the burden of taxation both upon the public and the medical profession, which is concerned with the care of the sick.

V In the matter of Federal Compensation practices, the Public Relations Committee sent a telegram January 2, 1934 to the President of the United States, and other officers of the Government, as printed in the *New England Journal of Medicine* of January 11, 1934

'AN URGENT PROTEST ADOPTED AT A MEETING OF THE COMMITTEE ON PUBLIC RELATIONS HELD IN BOSTON, JANUARY 2 1934 Whereas the Civil Works Administrator of the United States Harry L. Hopkins, has instructed John J. Morris, Counsel for the Civil Works Administration of Massachusetts, to place all employees injured in the Civil Works program under the Federal Compensation Act and

TREATMENT OF HYDROCEPHALUS BY
ENDOSCOPIC COAGULATION OF THE CHOROID PLEXUS*

Description of a New Instrument and Preliminary Report of Results

BY TRACY J. PUTNAM, M.D.†

HYDROCEPHALUS of the communicating type has been so long recognized as a progressive and usually fatal disease that many attempts have been made to devise methods of relieving the condition by operation. The history of the subject has been ably reviewed by Davidoff¹ and we see from his paper that although many of the suggested operative procedures are extremely ingenious and occasional good results have been reported, none of them have become widely accepted. Dandy² as a result of considerable experience regards third ventriculotomy as the method of choice. The operation which has apparently yielded the best results at this hospital is that at first advocated, but later abandoned by Dandy², namely, removal of the choroid plexuses of both lateral ventricles by open operation. While no extensive statistics have been reported, some patients are still alive months after the operation, without progression of symptoms. Judging, however, from the experiences of neurological surgeons in this community (including my own) the operative mortality is high. Even when life is prolonged, the end results are apt to be disappointing, for the manipulation involved in emptying the ventricle and retracting its walls to expose the plexus almost inevitably leads to extensive cortical damage.

Believing that the principle of Dandy's operation is physiologically sound it occurred to me that it might be carried out by an endoscopic procedure. Dr. W. Jason Mixer showed many years ago that it is perfectly feasible to examine a hydrocephalic ventricle by means of an urethroscope³, and was kind enough to place his instrument at my disposal. But this, and all the other endoscopic devices ordinarily available proved to have certain disadvantages (such as focal length of lens system, inadequate field, bulk, etc.) which rendered them unsuitable for the purpose. Experience with microscopy of the choroid in animals⁴ showed that actual contact of the instrument with the plexus was essential for accurate vision in a cloudy medium. The necessities of a device to employ the coagulating currents of a modern diathermy generator made the use of a metal sheath disadvantageous.

Finally actual experience at the operating table dictated the shape and dimensions of the completed apparatus⁵.

The coagulating ventriculoscope (figs. 1 and 2) in its present state consists of a rod of optical glass with polished ends. The ventricular end is plane while the observer's end is ground with a slight curve of which the focal length is approximately equal to the length of the instrument. The rod bears a deep longitudinal groove in which lies a tiny bronchoscope light and its carrier. Two other smaller grooves carry the electrodes for diathermy, which are cemented to the glass and covered by an insulating enamel. The tips of the electrodes are bare, and are bent slightly toward each other so that they appear in the field of vision. The instrument is sterilized by immersion in alcohol, and is encased in a tube of rubber dam when in use. The ventriculoscope is made in two sizes, one ten centimeters long and six millimeters in diameter, the other eighteen centimeters long and seven millimeters in diameter.

The actual operation is carried out on one side at a time usually under avertin anesthesia. Ether should be avoided. A longitudinal incision is made through the scalp about three centimeters from the midline, in the parieto-occipital region. The bone is drilled and rongeured away over an area about four centimeters in diameter. The dura and then the pia are incised and clipped together to control bleeding and prevent collapse of the cortex. The handle of a scalpel is thrust through the white matter, and followed by the tip of the ventriculoscope. The room is then darkened and the operator puts on a sterile celluloid mask.

By careful maneuvering it is possible to follow the small veins on the walls of the ventricle down to the fossa in which the plexus lies. The plexus itself is a flocculent copper-red structure, floating free in the fluid. When the ventriculoscope is pressed against it and the coagulating current turned on sparks surround the electrodes and the tissue within the field turns white. Bit by bit most of the choroid in the body of the ventricle may be destroyed. In some instances there is a defect in the septum pellucidum, and the contralateral plexus may also be attacked.

Coagulation usually lasts five to twenty minutes. The patient often moans slightly when

From the Surgical Service of the Children's Hospital, Boston, and the Departments of Surgery and of Neurology, Harvard Medical School.

Read before the Boston Society of Neurology and Psychiatry May 17, 1934.

†Putnam—Professor of Neurology, Harvard Medical School. For record and address of author see "This Week's Issue" page 1394.

*I must acknowledge my indebtedness to Mr. Walter G. Wolfe of Pinkham and Smith Co., Boston, for his expert assistance with the optical system.

important than any one of them is the basic idea of inducing closer coöperation and contacts of neighboring practitioners. No one can do that for them and if they are unwilling to take so short a step, then we may expect them to wander farther in the wilderness.

In all of our work we should be concerned with the preservation of the precious traditions that have been ours through many previous decades and in the evolution and advance of the practice of medicine be solicitous that doctors should take the lead.

The Costs of Medical Care has had the earnest consideration of doctors philanthropic and economic agencies throughout the Commonwealth and we are inclined to urge that the community interests should solve the individual questions, thus achieving better personal results from the viewpoint of the patient and the doctor. Cities and towns are slow to believe that money spent for health and sanitation is either necessary or economically sound and we advise that doctors in their several communities become active participants in this campaign of education. Thus practitioners cooperating with each other and with local boards of health may attain results for the residents of a community through already existent facilities, or by such additions of personnel or buildings as may be determined to be necessary after sufficient study has been made to insure adequate solution of the problems presented. This means at least local public interest on the part of the medical profession in each city and town, and with one or more doctors willing to undertake this responsibility, we believe that the greatest service for the public and the medical profession would follow. The public health officer should be encouraged to call upon the local physicians for suggestions and coöperation, as poor sanitation and inefficient control of communicable disease mean 'poor medicine' and the public should be taught and is willing to look to the medical profession for its welfare under all conditions.

APPENDIX NO. 9

OFFICIAL COPY OF ACCEPTED RESOLUTIONS OF THE
RESOLUTIONS COMMITTEE OF THE NORFOLK DISTRICT
MEDICAL SOCIETY

Whereas free and nearly free treatment privileges in municipal and endowed charitable hospitals are

designed primarily for the indigent and when properly managed meet with the approval, coöperation and support of the medical profession, and

Whereas the growing extension, in each institution, of this care and treatment to the non-indigent results in a lessened efficiency and a comparative neglect of the deserving people for whom these privileges are established, and

Whereas this recognized abuse of such medical charity often results in unwitting and unfair competition with the private physician by these supposedly charitable institutions, therefore

Be it resolved that

1 The Norfolk District Medical Society through its Councilors urge upon the Massachusetts Medical Society the need for immediate corrective action to speedily bring relief from the aforesaid existent conditions through appropriate legislation and all other necessary measures.

2 The Norfolk District Medical Society through its proper officers and committees bring the matter at once to the attention of His Honor, the Mayor of the City of Boston and to the proper authorities of the various charitable hospitals in Greater Boston, urging that these cited abuses and impositions be discontinued and that every effort be made to correct and eradicate them.

3 There be established in Boston by the municipality or by the coöperation of private agencies representative of the charitable hospitals, or both, a duly accredited agency or clearing house which shall investigate the financial status of all applicants for medical charity, in any and all branches and which shall be empowered to issue suitable and certified credentials to those found worthy of gratuitous treatment.

4 Pending the establishment of this proposed agency or clearing house, each institution in question be urged to make every effort to expedite the correction of these existing abuses by the signed statement of each applicant in affirmation of the necessity for gratuitous treatment, further, to display in such a manner as to be easily read by all applicants for charitable aid, in any and all branches, a suitable sign indicating clearly that the institution, or at least that particular department, is for charity patients only and is not open to those financially able to pay a fee to a physician, and finally, should it be learned at any time that this entrance requirement has been ignored by any applicant, a penalty of the immediate termination of treatment shall be exacted.

5 Copies of this resolution be placed in the hands of neighboring district societies with the request that such societies join with the Norfolk District Medical Society in this movement to correct and eradicate the aforesaid abuses of medical charity.

Signed

FREDERICK L. HAYES *Chairman*,

sure that the condition is arrested. The sixth child, an intelligent girl of fifteen months had a head which measured seventy-three centimeters before the second operation, and sixty-seven centimeters three weeks later. At present, seven weeks from operation, there appears to be an obstruction of the aqueduct doubtless from a

SUMMARY

1 A new endoscopic instrument is presented with which it is possible to destroy the choroid plexuses within the lateral ventricles by means of electrical coagulation without removal of spinal fluid.

FIG. 3. P. W. aged four weeks at time of first operation (left) and two months later (right) to show collapse of the fontanelle following coagulation of the choroids.

clot, which will probably require further attention.

It is difficult to judge accurately of an infant's mental capacity, but at least four of the patients in the present series appeared normally active and bright. Two of those with the largest heads appeared alert and intelligent. The procedure had no apparent effect on mentality in any of the cases. Two patients had a few convulsions in the first two weeks postoperative. No other abnormal neurological manifestations ascribable to the operation have been made out.

Considering the otherwise almost hopeless outlook for the disease, the immediate results appear encouraging. It remains, of course, to be seen what the final outcome will be, but it seems reasonable to suppose that it should be at least as good as that of the cases in which the choroid has been removed by open operation, in some of which it appears that permanent relief has been obtained.

2 The procedure has been used in seven cases of communicating hydrocephalus in infants and one of meningocele without hydrocephalus with encouraging results so far. Bulging of the fontanelles has been relieved and the diameter of the head has been decreased in all cases except one.

3 There have been two deaths in the series, both due to intercurrent diseases and possibly not to be attributed to the operation. The intracranial pressure was relieved up to the time of death in these cases also.

the current is turned on. The instrument is finally withdrawn, and the wound carefully sutured. The reaction to the operation is slight, and directly proportional to the amount of hemorrhage. Often the infant will be able to take its feedings the same afternoon. In some in-

Two of the children in the series have died, but it seems fair to question whether either death should be ascribed to the operation. The first case was that of a mentally retarded girl of four months, whose head had grown to the size of thirty-one centimeters following an oper-

FIG 1 The two models of the coagulating ventriculoscope. The larger model is shown assembled with light carrier in place. The lamp and carrier are shown separated from the smaller model. The heavy wires attached to the observer's end of both instruments are for the coagulating current.

stances, there has been no perceptible change in the clinical chart to mark the day of operation.

Endoscopy with coagulation has been carried out twelve times in seven unselected cases of hydrocephalus—all those brought to the Sur-

FIG 2 Enlarged view of the ventricular end of the larger instrument to show the electrodes.

gical Service for treatment within the last five months. The infants varied in age from one to eighteen months at time of operation. In most of the cases, hydrocephalus had come on following operations for meningocele. In an additional case the choroid was coagulated to relieve the pressure within a meningocele although the head was not enlarged at the time, and the results appear to justify the step

ation for meningocele. The choroid was coagulated on the right, and a week later on the left. The child was doing satisfactorily after the second operation and the head had decreased to a diameter of twenty-nine centimeters, when the family became uncooperative and insisted on taking her home. She died of a respiratory infection about a week later.

The second fatal case was that of an apparently bright male infant of about a month, whose head measured forty-five centimeters in diameter, and was growing progressively. The fontanelle was tense. Coagulation of the choroid was carried out on one side with little immediate reaction, and the baby did well for two days, but then developed diarrhea and died a week after operation.

Of the six remaining patients three who have survived the operation for seventeen (fig 3), five and four weeks respectively, appear to be definitely relieved at present. Their heads have remained stationary or decreased in size, and the fontanelles have become sunken. The pressure has been definitely decreased in two other cases still in the hospital, but it is too early to be

such a case. For this reason the records have been analyzed of twenty-nine cases of pancreatic necrosis, twenty-two cases of chronic pancreatitis, and twenty-four cases of focal fat necrosis of the pancreas which have been observed in the Pathological Laboratory of the Boston City Hospital, in order to gather more information regarding the factors associated with these conditions. Especial attention has been directed to the occurrence of these conditions in association with acute and chronic alcoholism.

TABLE 1
CONDITIONS ASSOCIATED WITH ACUTE AND CHRONIC LESIONS OF THE PANCREAS

	Acute Pan- creatic Necrosis	Chronic Pan- creatitis	Focal Fat Necro- sis
<i>Cirrhosis of Liver</i>	2	5	7

(? Alcoholism 3)			
<i>Pregnancy</i>	1	—	—
<i>Extension Ulcer of Stomach and Duodenum</i>	2	—	1
<i>Tuberculosis</i>	—	—	2
<i>Diabetic Coma</i>	—	—	1
<i>Cardiac Insufficiency with Congestion</i>	1	2	3

The results of the study of these records are summarized in table 1. The distribution of the associated conditions was similar in all three groups, that is to say, these pancreatic lesions were found to occur in patients with alcoholism or diseases commonly associated with chronic alcoholism in approximately one-third of the cases. Indeed, of the nine cases of pancreatic necrosis in which the cause was obscure, it is probable that three additional cases were associated with alcoholism. Of the cases of chronic pancreatitis, in which the predisposing factors were undetermined, a few were associated with obesity or arteriosclerosis. In some of the history concerning drinking habits was inadequate so that it is impossible to say whether any of these cases might have resulted from alcoholism.

Abstracts of the records of the six cases of pancreatic necrosis following alcoholism are briefly given.

REPORT OF CASES

CASE 1 A young man thirty years of age was admitted to the hospital complaining of abdominal pain and vomiting of one week's duration. For about fourteen months prior to admission he had been drinking very heavily, and frequently drank as much as a quart of alkyl spirits a day. Twelve months before entry he had an attack of nausea and vomiting which lasted for six days. On numerous occasions following an alcoholic spree he would have intermittent abdominal pain and vomiting.

Six days before admission to the hospital following a bout of drinking he was seized with severe epigastric pain and vomiting. The pain was constant and accompanied by four or five attacks of vomiting a day and obstipation. He had felt hot and flushed and had been in bed for three days before admission.

Upon examination the patient appeared acutely ill. He was mentally clear and alert and complained only of abdominal pain. The temperature was 104°F, the pulse rate 160 per minute and the respirations were 26 per minute. The face and extremities were cyanotic with a yellowish tinge. The heart rate was rapid but the sounds were clear. The lungs showed nothing abnormal. The abdomen was distended but everywhere tympanic without evidence of free fluid. There was tenderness and some rigidity of the abdomen above the umbilicus and some pain and tenderness in the left flank. A friction rub was heard over the liver below the rib margin on the right side and normal peristaltic sounds could be heard with the stethoscope.

The white blood count was 15,100 per cubic millimeter with 87 per cent polymorphonuclear cells. The icteric index was 100 units and the non-protein nitrogen of the blood was 40 mg per cent.

A laparotomy was decided upon and a typical hemorrhagic pancreatitis was found. There was no evidence of obstruction in the bile ducts. The capsule of the pancreas was drained. The patient died one hour after the operation. There was no autopsy.

CASE 2 A white man aged forty-three years who had drunk alcohol to excess was admitted to the hospital on account of abdominal pain, fever and jaundice. He had had two similar attacks during the past two years. The onset of the illness had been abrupt with abdominal pain, nausea and vomiting. Upon examination there was icterus, tenderness in the epigastrium and a palpable mass beneath the liver. The temperature varied from 100°F to 102°F and the jaundice persisted. Three weeks after the onset the patient was operated upon; an abscess under the liver was incised and drained. The pus contained *B. coli*. Following the drainage of the abscess the edges of the wound showed evidences of digestion. The patient failed gradually and died one month after the onset of the acute symptoms.

Anatomical Diagnosis Suppurative pancreatitis. Localized peritonitis. Retroperitoneal abscesses about the tail of the pancreas. Thrombosis of splenic artery. Infarcts of spleen. Jaundice. Obesity. No evidence of cholelithiasis.

CASE 3 A white woman twenty-seven years of age drank daily large quantities of whiskey for three weeks prior to admission. This was followed by severe nausea and vomiting of several days' duration, then there appeared severe pain in the abdomen especially over the left hypochondrium. The size of the abdomen was increased. Examination revealed an obese woman with rapid thready pulse, cold clammy skin, no elevation in temperature and a large firm tumor filling the whole left side of the abdomen. There was tenderness over the tumor. At

ACUTE PANCREATIC NECROSIS IN ACUTE AND CHRONIC ALCOHOLISM*

BY WALTER K MYERS, M.D.,† AND CHESTER S KEEFER, M.D.†

EVERYONE who has had an opportunity to study a group of cases of acute pancreatic

*From the Thorndike Memorial Laboratory Second and Fourth Medical Services (Harvard) Boston City Hospital and the Department of Medicine Harvard Medical School

necrosis has commented upon the fact that alcoholism is a predisposing factor. A few clinicians have observed cases of pancreatic necrosis following bouts of acute alcoholism, but its occurrence under these circumstances is not generally appreciated. We have recently observed

dominal pressure, as occurs with vomiting and retching. Others have reported cases of pancreatic necrosis following vomiting and retching as a result of general ether anesthesia.^{7, 8} It is possible that the development of acute pancreatic necrosis following vomiting will depend to some extent upon the exact anatomical relationship of the opening of the pancreatic ducts into the duodenum. That is, pancreatic necrosis may follow vomiting and retching if the pancreatic ducts open directly into the duodenum. These questions must remain unanswered for the present.

THE DIAGNOSIS OF PANCREATIC NECROSIS

The diagnosis of pancreatic necrosis is made from an appreciation of the predisposing factors, a knowledge of the clinical features, the

conditions in which pancreatic necrosis may occur. Some are rare. In others the pancreatic process is but a part of the primary condition. However, a full appreciation of the etiologic or predisposing factors is essential in arriving at a correct diagnosis.

Attempts are made to divide acute pancreatitis into various types: hemorrhagic, gangrenous, and suppurative. From a study of any group of cases it seems apparent that in each one there is essentially the same process. Such a classification seems to be no more than a fine differentiation of the degree of involvement and the stage of the disease. The term *pancreatic necrosis* would seem to be more satisfactory. The clinical picture may be divided into (1) the acute process, and (2) the complications arising from the necrosis.

The onset of pancreatic necrosis is characteristically sudden following a large meal, an alcoholic bout or previous attacks of biliary colic, or without warning. Severe pain is the outstanding feature. It is located in the epigastrium, in the left hypochondrium, in the back or in both loins. The pain is soon followed by the symptoms of collapse, the pulse is rapid and of poor quality, the blood pressure falls, the temperature may be low and cyanosis due to collapse may be a striking feature. In other words, there are the symptoms commonly associated with a large hemorrhage together with the agony of a visceral rupture. Vomiting is almost always present early and is repeated, frequent and severe. The respirations may be rapid and shallow.

Upon examination of the abdomen, distention of the epigastrium, with tenderness extending into the back especially on the left side, are prominent features. Rigidity is not usually so striking as in the rupture of gastric or duodenal ulcer. The distention may be so prominent that intestinal obstruction is suggested.

If the patient survives the acute attack, there may be improvement in from three to seven days. Then the temperature rises and the signs of a localized abscess may appear. Vomiting may increase or recommence. The epigastrium may remain full and tender. The symptoms are present of an abscess pointing into the loin, in the subdiaphragmatic region, in the epigastrium or extending into the retroperitoneal tissues and appearing in the scrotum. There may be the symptoms of hemorrhage into the gastrointestinal tract or into the retroperitoneum. The complications recorded in the thirty cases studied, together with those which may occur as indicated by the literature, are listed in table 3.

From table 3 it is seen that the complications are due to fat necrosis resulting from digestion of tissue or hemorrhage following the erosion of a blood vessel. Due to the anatomical posi-

recognition of the complications, and the consideration of the diseases with which it may be confused.

In table 2 have been included a great many

operation, this mass was covered with omentum and extended from the brim of the pelvis upward behind the stomach where it was adherent to the posterior wall, it contained serosanguineous fluid which was evacuated. Drains were inserted. After operation the patient developed the signs of fluid in the left pleural cavity and died six days later.

Anatomical Diagnoses Pancreatitis with cyst formation. Acute fibrinous peritonitis. Pleurisy with effusion (left). Early serofibrinous pericarditis.

CASE 4 A white man, thirty-three years of age, acknowledged excessive drinking for a period of ten years. Recently he had taken little food and had developed the symptoms and signs of multiple neuritis with pains in the arms and legs. For several days before admission he had had persistent nausea and vomiting without abdominal pain. Upon examination there were the signs of peripheral neuritis, and marked oral sepsis. The abdomen was soft and no masses or tenderness were made out. He continued to vomit for three days but there was no essential change in his general condition until the day of his death. Suddenly he complained of extreme weakness and developed the signs of collapse with a tachycardia, cold extremities, sweating and dusky cyanosis. Death followed shortly after the appearance of these symptoms.

Anatomical Diagnoses Pancreatic necrosis with peripancreatic perinephric and retroperitoneal hemorrhage on the left side. Fatty liver.

CASE 5 A woman aged forty-two years who had drunk four to five glasses of beer and about one pint of whiskey a day for several years was admitted to the hospital. For one month before admission she had been drinking more than usual. Three days prior to entry she began to vomit almost constantly and the abdomen became distended and tender. Upon examination she was found to be prostrated, the temperature was 100°F, the pulse rate was 100 per minute and the heart sounds were distant. The abdomen was distended, and there was tenderness in the epigastrium. The white blood count was 14,000 per cubic millimeter. For five days she remained in about the same condition with the temperature varying from 98°F to 101°F. She then failed rapidly and died.

Anatomical Diagnoses Cirrhosis of the liver with fatty changes. Sclerosis of the pancreas with multiple areas of acute fat necrosis. Edema of the brain.

CASE 6 A young man aged thirty years had been drinking to excess for three months. Ten days before entry he was seized with severe abdominal pain, vomiting and pain in the back. He was restless and delirious. The abdomen was distended and there was tenderness across the epigastrium with extreme pain upon pressure. The temperature was 99°F. The leucocyte count was 24,000 per cubic millimeter. At operation the omentum was found to be thickened and contained many areas of fat necrosis. The pancreas was enlarged and indurated. The gall bladder was distended but appeared normal. Death occurred six hours after admission.

Anatomical Diagnoses Acute hemorrhagic pancreatitis with fat necrosis. Fatty liver.

From these cases, there is no doubt that acute pancreatic necrosis is occasionally seen following acute alcoholism when there are no other demonstrable factors to account for it.

Similar instances of acute pancreatic necrosis following acute alcoholism have been noted by McWhorter¹, Scheel², Mondon³, and Émile and André⁴.

Mondon reported a case of a young man who was admitted to the hospital with alcoholism, vomiting and tachycardia. The necropsy showed a hemorrhagic pancreatitis with hemorrhagic infiltration of the stomach, duodenum and upper jejunum, and thrombosis of the terminal branches of the superior mesenteric vein and the coronary veins of the stomach. The interpretation of the sequence of events in this case was not clear. Of the cases described by Émile and André all five were diagnosed cardiac insufficiency. Three were admitted with the diagnosis of acute alcoholism, one with the diagnosis of chronic alcoholism, and in the fifth the history was obscure. Necropsy showed that death resulted from pancreatic necrosis.

Aside from the cases of acute pancreatic necrosis following acute and chronic alcoholism, chronic lesions in the pancreas are not uncommon in patients who have used large quantities of alcohol during life. Gross and Guleke⁵ discuss at length the rôle of chronic alcoholism as a cause of pancreatitis, especially the chronic forms of the disorder. They are of the opinion from their own experiences and from a study of the literature that patients with chronic alcoholism commonly show anatomical alterations in the pancreas. These lesions are described as an increase in the intra- and inter-lobular fibrous tissue. We were able to confirm this opinion.

Not uncommonly, in patients who eventually show the lesions of chronic pancreatitis, there is a history of previous attacks of upper abdominal pain. These attacks of pain, if any diagnosis was made, may have been called acute gastritis. On the contrary, in the cases in which fat necroses are found, the symptoms during life may not lead to a suspicion of pancreatic disease.

The mechanism whereby pancreatic necrosis follows alcoholism is not evident. Three possibilities are suggested: the effect of alcohol on the pancreas as it is carried to it by the blood stream, obstruction or infection of the pancreatic ducts due to duodenal congestion following acute alcoholism and the forcing of duodenal contents or bile into the pancreatic ducts as a result of persistent vomiting.

Objections to all three of these possibilities may be raised. It is probable that no one cause will be found. Chronic changes do occur in the pancreas in the absence of duodenal congestion or infection. If it is admitted that alcohol plays a rôle in the production of changes in the liver, it would be difficult to deny the possibility of similar processes taking place in the pancreas. The question of the regurgitation of duodenal contents into the pancreatic ducts during the act of vomiting is one which has excited controversies. Some physicians⁶ doubt that it is possible to force duodenal contents into the pancreatic ducts by increased intra-ab-

short time, so that its use externally is not advised, however, there still crops up a sporadic case where some person has used an arsenic paste on a cancerous lesion

Fowler's Solution, i.e., potassium arsenitis, is a drug which accumulates in the system and is bound to show itself in various pathologic forms later in life. This preparation was given publicity in the latter part of the Eighteenth Century by an English physician, Dr T Fowler, who called it "Liquor Mineralis" to deceive the patients regarding the presence of arsenic, he also reported that urticaria resulted from its use. According to "Remington's Practice of Pharmacy," the formula is as follows

Arsenic Trioxide	10 Gm
Potassium Bicarbonate	20 Gm
Compound Tincture of Lavender	30 cc
Distilled Water	qs 1000 cc

REPORT OF CASE

Mrs I. F. aged sixty-one, was first seen November 11, 1930 referred by Dr Joseph Lynch. She complained of itching and blotching of the skin.

Present Illness The patient stated that for the past seven years she suffered from marked itching of the skin which sometimes broke out into large marks like hives, and at other times left big ridges. This itching was so marked that it kept her awake at night and made her very nervous.

Past History She stated that twenty-eight years ago she had epileptic attacks for which she was treated by a local M.D. who gave her a medicine which she took continuously until five years ago. It cured her of her epileptic attacks but she was so afraid of their recurrence that she continued to take the medicine.

Physical Examination Showed marked eruption on body and extremities, the skin showed various sized lesions consisting of papules, vesicles, wheals of various sizes, numerous excoriations, and several areas of brownish pigmentation. Examination of the palms and soles showed a different type of eruption here the skin was very dry, and there were more or less symmetrically distributed definite hard, keratotic papules surmounted on a skin which was markedly thickened. General physical examination was negative except blood pressure which was 192/86. Briefly, this patient showed

typical arsenical dermatitis with keratoses, wheals, papules, excoriated vesicles, and pigmentation.

A copy of the prescription which she took for twenty-three years was secured and was found to be as follows

Pot Bromidi	dr 8
Tinct Nux Vomica	dr 4
Liq Pot Arsenitis	dr 2
Aquae	oz 1
Elix Gentian & Tr Ferr Chloridi	oz 6

This woman had taken over three drops of Fowler's Solution three times a day. She was given various treatments including the use of calcium gluconate and sodium thiosulphate and local applications which gave her some relief from the itching but no improvement of the keratotic lesions, itching was kept more or less under control until her last visit on February 13 1931. On April 30, 1931, she was seen by Dr Lynch and at that time, she complained of nausea (one week's duration) her left eye was blurry and she noticed a yellow appearance of her eyes and skin. Five days later she started vomiting this continued until she was sent to the hospital for further observation. At the hospital x-ray was employed but showed no definite pathology. The patient was operated upon March 22, with diagnosis of carcinoma at the head of the pancreas and the question of acute hepatitis. Under spinal anesthesia and with the usual abdominal preparations a high right paramedian incision was made. The abdomen was opened the liver was found to be reduced to two-thirds its normal size, and its surface was roughly granular. The gall bladder was not distended and emptied readily. There was no evidence of stones or of common duct obstruction. It was felt that nothing further was indicated from a surgical standpoint and the abdomen was closed in layers. The patient died eight days after operation.

Laboratory Findings Wassermann—Negative
Trace of bile in urine

The above case, as regards the skin, showed a typical eruption due to the ingestion of arsenic, and it was the opinion of the internist and surgeon that the liver changes were also due to arsenic. Whether the arsenic was of value in the original condition it is hard to state, but the continued use of this dangerous prescription could have been prevented by simply adding the words "non-repeat"

MALPRACTICE SUITS, THEIR CAUSE AND PREVENTION

BY HALBERT G STETSON, M.D.,* AND JOHN E MORAN, M.D.*

AN analysis of the causes of malpractice suits has been made and the following facts present a summation of information obtained from various liability corporations and physicians

Approximately twenty thousand suits have been brought against physicians in the United States in the past five years, nearly one thousand of which have occurred in Massachusetts. There are approximately 350 cases awaiting disposition in this state at the present time†

The causes of these suits, as determined from an analysis of 35,000 cases, are as follows

- 1 Inopportune remarks by subsequent attending physicians
- 2 Personal enmity and jealousy between members of the profession
- 3 Countersuits interposed as a defense against the suit brought by a doctor for the purpose of collecting his fee
- 4 Failure to use the x-ray in the diagnosis of, and reduction of, fractures
- 5 Outside causes, e.g., newspaper articles, so called "scientific cults," etc
- 6 Negligence of the nurse employed by a physician.
- 7 Rarely alcoholism

†Presented for publication January 27 1934

*Stetson—Surgeon Franklin County Public Hospital. Moran—Surgeon Franklin County Public Hospital. For records and addresses of authors see "This Week's Issue" page 1394

tion of the pancreas, most of the areas of necrosis or the hemorrhages are retroperitoneal and on the left side. If a blood vessel is not opened by digestion, it may become thrombosed. Symptoms resulting from this process will depend upon the vessel occluded.

The conditions that simulate pancreatic necrosis are the following: (1) perforated gastric or duodenal ulcer, (2) biliary colic or acute chole-

as well as the similarity of the symptoms. When confronted with an acute upper abdominal condition, it is necessary to consider pancreatic necrosis in addition to the more common conditions.

SUMMARY AND CONCLUSIONS

1. Acute pancreatic necrosis may occur following an acute bout of alcoholism, especially if there is prolonged nausea, vomiting and retching.

2. Pancreatic necrosis and chronic pancreatitis are found in conditions commonly associated with alcoholism, such as cirrhosis and fatty infiltration of the liver.

3. The various circumstances under which pancreatic necrosis occurs are presented together with the diagnostic features and complications as recorded in thirty cases.

4. Attention is called to the conditions in which mild attacks of pancreatitis may be observed.

cystitis, and (3) intestinal obstruction. Indeed, one of these diagnoses is usually made when pancreatic necrosis is later found to exist. This is, in no small measure, due to their frequency,

ARSENIC POISONING

BY JOHN G. DOWNING, M.D.*

JANUARY 6, 1934, three detail men left samples of so called tonics at my office, each containing arsenic, one label announcing arsenous acid gr 1/40 (16 mg.) to the dose, to be taken three or four times daily.

Shortly after their departure, a girl presented herself for the treatment of acne. She stated that she had been treated by her family doctor for the past year. At the beginning of the year he prescribed liquor potassium arsenitis in five-drop doses three times a day, and as she had had no relief after faithful ingestion of the above medicine for the full year, she decided to try another physician. At intervals during the year she inquired as to the feasibility of continuing the arsenic but was assured of its value. Lately she noticed that she was feeling quite depressed and languid. Later, upon examining various bottles and packages of pills in the sam-

ple closet, it was a revelation to find how many contained arsenic in some form. As a result I determined to report the following case as an example of the result of the injudicious use of arsenic. This routine giving of arsenic for so called "alterative," "tonic," "roborant," "blood builder" purposes is irrational and harmful.

Arsenic, for many years, was proclaimed the most useful drug in the treatment of skin diseases and has been employed in a large variety of morbid conditions of the skin, it is a useful though much overrated drug and most dermatologists are exceedingly careful in prescribing it. It certainly has a profound influence on the skin for it can produce any form of eruptive disturbance. The cutaneous eruptions from the external and internal use of the drug are similar in character. The irritant effect of external applications has been known since antiquity and cases are on record where arsenical lotions, plasters, and pastes have proved fatal in a very

"Absence of x-rays	
Diagnosis missed	56
Some complication overlooked	18
Malunion not recognized	12
Allegation by hostile practitioner could not be refuted	4
	90
Hostile action based on adverse criticism by another practitioner	10"

He also says, "Unfortunately the practitioner who carries out this treatment is often not content with having secured the patient, but allows himself to express some hostile criticism or at any rate assents to an opinion expressed by the patient, hostile to the first doctor. This opinion then actually forms the basis of the action for negligence. This factor of one medical man criticizing or condemning another is in reality very much more important than the figure of 10 per cent would indicate. The great majority of all the other 90 per cent of the cases, although they may turn upon the neglect of x-rays, are nevertheless supported by the criticism of one medical man about the conduct of another."

These suits form a very important problem. A recent speaker before the Franklin District Medical Society emphasized the caution that must be observed in caring for fractures. He stated that nearly 90 cases of fractures were pending disposition in malpractice suits in Boston at that time.

In view of the above analysis of 35,000 or 40,000 cases it might be well for members of the profession to remember the statement of Rip Van Winkle, made after one of Dame Van Winkle's outbursts of temper, "A tart temper never mellows with age, and a sharp tongue is the only edged tool that grows keener with constant use." The Greek philosopher, Xanthus, said, "The tongue is the best and worst in man, the best if used all right, the worse if used awry." If these two thoughts are kept in mind we are sure that malpractice suits will show a decided drop. The suggestions of Locke should be always kept in mind: "Please don't criticize—particularly to the patient—the treatment given by some other doctor before the patient came to you. You see the result—nothing more. You do not know the whole story. You do not know what the original condition was, what the other man encountered in the way of difficulties, or whether he had proper cooperation from the patient. Wait 'until the evidence is all in.' You may change your mind when you get all the facts. You may be wiser. But at least, you will know what you are talking about."

Adequate records and greatly in proper disposition of these cases. To quote Cannon: "To eliminate many of these dangers, I caution you as follows:

(1) Relative to your records. From day to day it must become more evident to the practicing physician and surgeon that his only safe-

ty against malpractice suits, even though he be guilty of no negligence, lies in keeping an accurate record of his treatment of the patient, not only a correct record in the hospital, but a correct office record of all that transpires outside of the hospital, and not only should he keep a correct record, but he should keep an accurate and detailed record, both in the hospital and out."

Copies of prescriptions should be kept, frequent roentgenograms should be taken, if an operation is performed the record should show what was removed, what was mended and what was learned. These records should be made at the time or immediately in one's recollection. In practically all of our malpractice cases, we find our records are not quite so complete as they should be. The writers have had little occasion to complain of the completeness of the records made by the attending nurse, whether it be the day or night nurse, these nurses seem to do their work well and carefully, their charts appear to be complete. But the so-called practical nurses are ignorant and some of them will be very glad of an opportunity to join in an effort to recover against the doctor. I might therefore, add that in addition to making complete and accurate records, the doctor "keep an eye" on the practical nurse.

Another caution might be suggested, and we approach that question with some misgivings. More frequent consultations should be had, bearing in mind, however, that the patient ought not to be required to pay too many doctors. The consultant ought not to work without reasonable recommendation. Good judgment should be used, and such judgment ought to indicate when a case is sufficiently serious or the family sufficiently dangerous to require consultation for the protection of the doctor and for the health of the patient.

Secondly. Wherever possible, have pathologic examinations made and records kept. The standardization of our hospitals has done much for you in this department, but all records should be checked from time to time, and it may be that your patient is not in a standardized hospital. Your records can nevertheless be made quite complete if you exercise care.

Thirdly. Do not hesitate to call an honorable and able professional man for consultation. You have nothing to fear from the man of honor and high professional standing. Lawyers do this, business men do it, all do it, and as a rule, the professional man of high ethics and good moral fibre will thank you for calling him, even if the patient is unable to pay, because it enables him to perform that high duty that he owes to humanity.

Fourthly. Secure consent before you operate, and if you have cause for suspicion that the parties are not of good character, require written consent to be signed. In major opera-

8 Rarely failure to use a method of treatment which is used by the majority or a respectable minority¹

Physicians are themselves to blame for the greatest percentage of suits. In replies to our inquiries, not one source of information put this cause below 60 per cent, while some placed it as high as 80 per cent. Inopportune remarks must be avoided. One must remember that, whenever a patient is dissatisfied with results, all that is necessary to start a lawsuit is the comment of some doctor, criticizing the work of a previous physician.

A considerable number of these suits are due to the specialist who, though he does not mean to, makes a statement which can easily be construed as meaning that the previously attending physician was negligent. One communication received states: "The specialist is unknowingly and unwittingly drawn into malpractice cases by the simple method of the patient presenting himself at the office of the specialist, often upon the advice of a lawyer who is somewhere in the background. The patient very cautiously gives little, if any, history of the attendance by a previous physician, seeks a diagnosis, which is usually given, and then never comes back. The specialist is very much surprised, in the course of two years, to be summoned as a witness for the plaintiff and have to give up time at the ordinary summons rate."

Inopportune remarks are the result of a lack of proper history taking and a poor knowledge of human psychology. By way of explanation, one has a patient with a poor result, the patient is in a state of self-pity, he then presents himself at the doctor's office. It is just the tone of the physician's voice when he says "Who treated you for this condition?" that increases the sense of self-pity and he brings in a malpractice claim. Then again, we have the type of physician who, without knowledge of the particular type of injury or sickness, or a knowledge of the particular patient that presents himself, will in some way lead that patient to believe that if he had come to him in the first place the present condition would not have occurred.

There is another class of "inopportune remarks" that causes malpractice suits. We have found that any number of doctors have been drawn into malpractice suits by simply answering hypothetical questions put before them by "lawyer friends."

The second group of causes consists of these factors: personal enmity, animosity and jealousy among members of the profession. One source of information writes: "We have seen a great many malpractice cases arise out of a personal enmity between physicians or between di-

visions of a local medical society. We have all ways felt that malpractice cases were not the place to get even. A malpractice suit that is successfully prosecuted tends to breed other cases of a similar nature and the activity of a physician in assisting a plaintiff in one case may ultimately result to his own detriment."

Another source states, "Our experience and the impression created in reading the statements of various doctors in regard to these cases in several thousand instances, lead us to believe that this personal equation is one which is a personal factor in causing these suits to be brought." There are many communities where such a feeling exists. One letter states: "There is also a breaking away from the old situation of physician and patient, probably due to a transient or floating population, plus a certain foreign element. With this situation in mind, all physicians should be very guarded in taking a case of another physician. We have noticed, too, that there is a slacking off in the subsequent attending physician calling up the previous physician and telling him that the patient has come under his care. This courtesy of ethics seems to have fallen by the wayside. It is my opinion that, if this little courtesy were adhered to, the average physician would save himself a lot of trouble. In the final analysis, as previously stated, about 65 per cent of the present claims were due to the remarks made by subsequent physicians. Of this amount we would say that at least 45 per cent were incautious remarks, not made with any malicious intent, or even no remarks made at all, but mere gestures or acts of the subsequent attending physician, from which the patient drew an inference that he had been wronged. The other 20 per cent were undoubtedly due to professional jealousy, self-assurance and superiority psychology."

Such statements should make physicians everywhere realize that clean, straightforward adherence to the codes of professional ethics will do much to lessen the incidence of such claims. For men to feel that they possess far greater skill than a group of equally capable men in the same community, is mere conceit. It would be much better for such groups to meet and develop good fellowship than to allow them to remain isolated from each other.

The estimate of counterclaims brought because a physician attempts to collect a bill is twenty per cent. In view of this, it is well to remember the time at which malpractice suits are outlawed. In this state it is two years, though some of our citizens would like to have the time extended.

In the case of fractures, Groves² found causes as follows:

stances talk with him, then advise him as to what we think he should do. If he needs our help we give it, not as a committee, but as individuals. The lawyers here quite generally understand it. In fact, one lawyer called a doctor to his office, told him he had been asked to bring a suit against him and advised him to bring the matter before the committee. He did so and when the lawyer found we had exonerated him, he dropped the case.

"The committee is made up of men who stand very high in the profession and when a lawyer knows that such a set of men have investigated a case and decided that the doctor involved is not guilty of malpractice, he is very shy about bringing a suit. The worth of such a committee has been recognized and now each county has a similar committee and the chairmen of the County Committees constitute a State Committee. A doctor who has a hearing before his County Committee and is aggrieved at their findings, can ask for a hearing before the State Committee."

Conclusions

1 An analysis of the causes of from about 35,000 to 40,000 malpractice suits has been made.

2 Sixty per cent are the result of inopportune remarks of a subsequent attending physician either because of the lack of

knowledge concerning the facts of a case or because of personal animosity or jealousy.

3 Twenty per cent are counterclaims made because the physician attempted to collect his fee.

4 Ten per cent are due to non-use of the x-ray in the diagnosis and reduction of fractures.

5 Ten per cent are due to outside causes as newspaper articles and so called "scientific cults," negligence of nurse, alcoholism, failure to use treatment, etc.

6 The following rules are the best safeguards against malpractice.

- a A cautious tongue
- b Proper use of the x-ray
- c Accurate and complete records
- d Adherence to the code of medical ethics and the application of the golden rule in the care of patients who have been previously attended by another physician
- e A knowledge of the accepted forms of treatment

NEW ORDER SPEEDS UP ERADICATION OF CATTLE TUBERCULOSIS IN TWENTY-FIVE STATES

The expansion of bovine tuberculosis-eradication work by the Federal Bureau of Animal Industry as a part of the emergency animal disease eradication program under provisions of the Jones Connally act will be governed by new regulations just approved by the Secretary of Agriculture. The first allotments of these funds, a total of \$2,000,000, are for cattle tuberculosis work alone and will be spread over twenty-five states as previously announced. The regulations, designated as B. A. I. Order 344, specify the method of conducting the work, the basis of making appraisals of tuberculous cattle and explain the requirements for cleaning and disinfecting premises and conveyances.

The new regulations differ from those used in the regular conduct of the work principally in allowing states to participate in eradication work whether or not they expend any of their own funds for indemnities or for the cost of testing. The total amount received as indemnity from all sources plus the salvage obtained shall not exceed the appraised value or an amount the owner would receive under the existing plan in his state. The payments for cattle found to be tuberculous will be made on the basis of a maximum of \$20 a head of Federal money for grade cattle and \$50 for registered pure-bred cattle.

MORTALITY RATES

Telegraphic returns from 86 cities with a total population of thirty-seven millions for the week ending June 9 indicate a mortality rate of 11.4 as against a rate of 11.1 for the corresponding week of last year. The highest rate (20.2) appears for Memphis, Tenn., and the lowest (4.6) for Long Beach, Calif. The highest infant mortality rate (21.4) appears for Spokane, Wash., and the lowest for Cambridge, Mass., Canton, Ohio, Duluth, Minn., Long Beach, Calif., Louisville, Ky., New Haven, Conn., and Somerville, Mass., which reported no infant mortality.

The annual rate for 86 cities is 12.3 for the twenty-three weeks of 1934, as against a rate of 11.7 for the corresponding period of the previous year.

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS) FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS OF 1934 AND 1933

	Week ending		First 23 weeks	
	June 9	June 10	1934	1933
	1934	1933		
Total deaths	162	140	3,627	3,167
Death rate	22.6	19.5	22.0	19.2
Deaths due to accidents in city	118	111	2,921	2,538
Death rate	16.4	15.5	17.7	15.4

tions the patient is under complete anesthesia. The physician may discover conditions not anticipated before the operation was commenced and which if not remedied will endanger life or health. In such cases he may, and perhaps in aggravated cases must, remove the newly discovered danger, but it is always wise to get consent to this action, and the surgeon who does not do so is not using that precaution in his own behalf that bespeaks his care in behalf of others. While the pathologic requirements of the hospital, if the patient is in a standardized one, is some protection, the careful surgeon will require still greater protection, because it is a principle of law that one's body is not to be mutilated in any manner except by one's consent. There are exceptions, for instance, one may be carried to a hospital in an unconscious condition with no one to speak for him, if not operated upon, he may die. But the exception is not the rule.

We do not wish you to believe that it is our view that the physician or surgeon is never at fault. We have lazy doctors as we have lazy lawyers, and others, who neglect their cases as the lawyer neglects his, who fail to keep abreast of the advancement of medical science and skill, as the lawyer fails to read the decisions and takes his cases in a slipshod manner. If his laziness in attending to the case or his laziness in keeping abreast of his profession results in damage to the patient who places himself in his charge, this doctor should be punished, and the way to punish him, outside of your profession, is to make him pay damages. But the best way to punish him is within your organization. Occasionally a good man is unable to defend himself because he has failed to protect himself by keeping records, and is unable to show what he did do.

We now have but 10 per cent left, due to other causes. Cannon seems to sum these up extremely well. "The outside causes of suits against doctors are many. People of the present day, without appreciating the fact that a little knowledge is a dangerous thing, read articles found in newspapers, some of them written by advertising doctors, and think from such reading that they know something about medicine and surgery, and they become critical. The smattering of knowledge that they have leads them to become fault-finders, and they love to profit by their fault-finding."

"Still another cause of trouble is the fake doctor. Never in the history of medicine have we had so many 'isms' in the medical and surgical field. To repeat the scientific names which men and women attach to themselves to fool the public into believing that they have scientific knowledge, would tax one's memory. Many of these affixes or prefixes mean nothing to the educated mind, but mean much to the public. Ignorant people go to these men after

they have been ill or have suffered an operation, and they leave firmly convinced that their former physician or surgeon has ruined them forever. These people cause trouble."

To think that because he is insured he does not pay, is incorrect. The policyholder, the one insured, always pays. The truth of this is well shown by the fact that in any form of insurance, if the amount deposited by policyholders is not enough for the company to carry out the agreement, they, the policyholders, must pay more money because the insurance company will be compelled to increase the rate on future insurance. The New Haven Medical Association had this very experience a few years ago. Their insurance company in seven years expended \$44,597. The amount deposited by the group with the company was \$18,127. The company then notified the Association that payments in future must be four to six times more than had been previously paid.

To say that the incidence of suits cannot be decreased is fallacious. The work of the New Haven Medical Association in decreasing the suits in their territory is commendable. They organized a committee on Medical Ethics and Department. The work of this group, and the results, can be best brought out by quoting from a letter received from the chairman, Dr. Frank H. Wheeler. "As to the percentage of suits started by indiscreet or malicious remarks of another doctor, it is hard to estimate. Our committee, as you will note, put it at 75 per cent. I saw an estimate the other day by some doctor as 80 per cent. We found that not only an injudicious word, but even the lifting of the eyebrows or shrug of the shoulders when examining a case treated by another doctor was enough to start a suit. Such an occurrence repeated to a shyster lawyer is often enough to start him making trouble for a doctor."

"Our committee was organized about a year and a half ago. There were several suits then pending. We investigated several of them and gave advice as to their handling. In four cases we advised settlement as the doctor was evidently at fault. One was settled, but the insurance company elected to contest two, and lost them. The fourth has not come to trial. We advised fighting the others. One of these has been tried and the doctor won. The others are resting in abeyance."

"Since the committee was formed several cases have been threatened. We investigated them and advised settlement in one, and in all the others we advised resisting. It would appear that nearly all of these latter have been dropped. No suits have been brought."

"I would call your attention to the name of our committee. It is not a defense committee. We are not appointed to defend a doctor, but when a member of our Association is accused of any misdemeanor we investigate the circum-

CASE 20261

PRESENTATION OF CASE

A fifty-six year old American widow entered complaining of pain in the lower abdomen of six weeks' duration.

Six weeks before admission the patient awoke at night with severe griping colicky pain across the lower abdomen. She vomited small amounts of frothy fluid. During a bowel movement that evening she had excruciating colicky pain in both lower quadrants running down over the pubic region, more marked on the right with some radiation throughout her entire abdomen. She had no urinary disturbance except slight frequency. There was no burning or urinary clouding. She continued to have similar attacks of pain during the intervening six weeks, and took considerable morphine for relief. Associated with this pain she had increased constipation, her bowels moving only once in three or four days despite the taking of cathartics. For the past two weeks she had had a slight dry cough and for the past week a small amount of ankle edema. One week before admission while lying in bed she found that she could not use her right leg because of severe groin pain. During the past four days the lower abdominal pain had become more severe and had been associated with marked tenderness in the right lower quadrant, flank and groin. The bowels moved slightly, with apparently normal feces. Two days before admission she vomited a small amount of light frothy fluid during an attack of abdominal pain.

The patient had had diabetes for fifteen years and had been given a diet with instructions for testing her urine. Under this régime her urine had been sugar free for about half the time and slightly positive for the remainder. She had had a little burning upon urination, but no clouding of the urine.

Her family and marital histories are non-contributory.

Physical examination showed a fairly well developed and nourished woman appearing acutely ill. The pupils were small and reacted sluggishly. The upper teeth were false. The tongue was coated. Examination of the chest was negative. The blood pressure was 125/80. The abdomen was moderately distended and tympanitic.

There was extreme tenderness over the right lower quadrant flank and costovertebral angle. There was moderate tenderness in the right inguinal region but no evident glandular enlargement. Peristalsis was normal. Rectal examination showed a small external hemorrhoidal tab. There were marked tenderness and spasm high up on the right. Pelvic examination showed extreme tenderness and firm resistance high up on the right. There was moderate edema of both lower legs.

The temperature was 101.1° , the pulse 100, the respiration 20.

Examination of the urine showed a slight trace of albumin and a slight trace of sugar. There was a very small amount of acetone, but no diacetic acid. Examination of the blood showed a white cell count of 58,000. One examination of the stool was guaiac-negative. A Hinton test was negative. The blood sugar was 200 milligrams per 100 cubic centimeters, the non-protein nitrogen 32 milligrams, the carbon dioxide combining power 58.2, the serum protein 6 per cent.

A flat x-ray film of the abdomen showed an enormous amount of gas in the colon extending from the splenic flexure to the cecum.

Operation was performed. She did poorly after it. Her white cell count was 26,600. A red blood cell count done on the day following operation was 2,750,000, with a hemoglobin of 35 per cent. A transfusion was done. Her diabetes was fairly well controlled, but she became semicomatose and died four days after admission.

X-RAY INTERPRETATION

DR. TRACY B. MALLORY: Will you comment on the x-ray films, Dr. Holmes?

DR. GEORGE W. HOLMES: This film shows a distended large bowel. The distention is most marked in the cecum and ascending colon and apparently stops rather abruptly near the splenic flexure. There is gas beyond this bowel, but I think it is in the small bowel.

DR. HENRY H. FAXON: Dr. Holmes, could you see diverticula without barium in a film of that kind?

DR. HOLMES: I think not.

In addition she has marked calcification of the pelvic arteries and a shadow in the pelvis which might be a calcified fibroid.

I should like to be able to go a little farther in an attempt to locate the obstruction. If this were large bowel we should expect to see the haustral formation in it that we see here. This is distended bowel, not paralyzed bowel. If the obstruction were low down we should expect gas to show in the whole length of the colon. It would seem that if there is an obstruction it must be above the pelvic rim.

BACKWARD DISPLACEMENT AFTER ANKLE FRACTURE

Corrective Operations

BY FREDERIC JAY COTTON, M.D.,* AND GORDON MACKAY MORRISON, M.D.*

NOT unusually fractures at the ankle with backward dislocation of the foot are followed by crippling disability. If possible this should be a matter of one cut, with removal of the

The problem of relief forces us to define two classes

1 Those in which backward dislocation of the foot and fragment give an inadequate (often unstable) weight-bearing joint with malleoli much displaced, and

2 Those with a decent enough, though not normal, weight-bearing joint disabled by painful contact at the front of the joint on motion, in dorsiflexion

For the first class nothing is of avail save an extensive reconstruction of the whole ankle, a useful operation, though formidable. The malleoli are divided at the joint level, and from the cut of the outer malleolus, the joint is opened horizontally forward. The malleolus then dragged down a bit gives access to the side of the tibia. With a large chisel (of wide curved concavity) a single cut is made horizontally across the joint, leaving a quarter cylinder concave cut (see first illustration) for the astragalus to set into. The next step is to loosen up the whole joint. This means extensive ligament tearing by external force or (not so good) instrumental leverage within the joint. This must be complete enough to allow of the astragalus being dragged forward (see second illustration) to a proper position. Sometimes the malleoli must be refitted. Pins or the like are not needed. Inasmuch as the cartilage of the top of the astragalus is not cut and should not be bruised, direct ankylosis does not occur. The results are rather better than one might reasonably expect. In the lesser cases, the remedy is less. One need only abolish the check to dorsiflexion. That means an incision on the outer side of the joint, a thin osteotome slipped in so sloped as to clear a generous wedge straight across the front of the tibia. (See lower figure

TYPE III.—COTTON FRACTURE

Upper figure left—
(a) shows the approximate line of the posterior tibial fracture

The astragalus is in contact with the rear fragment but out of weight bearing contact with the main articular surface of the tibia. Dorsal motion absolutely blocked. A new curved articular facet is cut in the tibia (b) to receive the top of the astragalus.

Upper figure right—
This cylindrically concave surface is shown by the heavy line. Into it the astragalus is fitted. No attempt is made to move or remove the projecting (and very inaccessible) posterior fragment.

Lower figure
(a) line of break (b) edge of tibia removed to clear dorsal flexion—and with it a space gouged out of the astragalus to give more room.

wedge in one piece. If there has been much irritating contact the neck of the astragalus may show overgrowth, and may be dug away, liberally. One need not fear ankylosis for there is no longer any bone contact. The only chance is of a recurrence of bony overgrowth. As a rule the operation, very simple as it is, is well worth while.

*The type sometimes called Cotton's fracture.

*Cotton and Morrison—For records and addresses of authors see page 317 issue of April 12, 1934.

IMAGINARY ILLS

In an address before the American College of Physicians at its recent meeting, Dr. Edward Weiss of Philadelphia stated that a large number of people believe that they are ill but without any real basis for this fear. This opinion was based on the results of a poll of medical school professors who have found that thirty-five per cent of those seeking professional help were the victims of emotional problems.

Many operations have been performed to rid patients of imaginary troubles, according to Dr. Weiss

He cited one case of a young woman who was subjected to four operations because of symptoms which had no pathological evidence of organic trouble. In this case the symptoms were brought out by the fact that all of her sisters were married and the patient feared that she would have to remain a lonely spinster.

This seems to indicate that her surgeons had no adequate knowledge of the necessity of the services of the psychoanalyst, and sustains the contention that psychiatry is a neglected subject in medical education.

nitic. There was extreme tenderness over the right lower quadrant, flank and costovertebral angle. There was moderate tenderness in the right inguinal region but no evident glandular enlargement. Peristalsis was normal. Rectal examination showed a small external hemorrhoidal tab. There were marked tenderness and spasm high up on the right. Pelvic examination showed extreme tenderness and firm resistance high up on the right. There was moderate edema of both lower legs.

The temperature was 101.1° , the pulse 100, the respiration 20.

Examination of the urine showed a slight trace of albumin and a slight trace of sugar. There was a very small amount of acetone but no diacetic acid. Examination of the blood showed a white cell count of 58,000. One examination of the stool was guaiac-negative. A Hinton test was negative. The blood sugar was 200 milligrams per 100 cubic centimeters, the non-protein nitrogen 32 milligrams, the carbon dioxide combining power 58.2, the serum protein 6 per cent.

A flat x-ray film of the abdomen showed an enormous amount of gas in the colon extending from the splenic flexure to the cecum.

Operation was performed. She did poorly after it. Her white cell count was 26,600. A red blood cell count done on the day following operation was 2,750,000, with a hemoglobin of 35 per cent. A transfusion was done. Her diabetes was fairly well controlled, but she became semicomatose and died four days after admission.

X-RAY INTERPRETATION

DR. TRACY B. MALLORY: Will you comment on the x-ray films, Dr. Holmes?

DR. GEORGE W. HOLMES: This film shows a distended large bowel. The distention is most marked in the cecum and ascending colon and apparently stops rather abruptly near the splenic flexure. There is gas beyond this bowel, but I think it is in the small bowel.

DR. HENRY H. FAXON: Dr. Holmes, could you see diverticula without barium in a film of that kind?

DR. HOLMES: I think not.

In addition she has marked calcification of the pelvic arteries and a shadow in the pelvis which might be a calcified fibroid.

I should like to be able to go a little farther in an attempt to locate the obstruction. If this were large bowel we should expect to see the haustral formation in it that we see here. This is distended bowel not paralyzed bowel. If the obstruction were low down we should expect gas to show in the whole length of the colon. It would seem that if there is an obstruction it must be above the pelvic rim.

FURTHER HISTORY

The operation was incision and drainage of a retroperitoneal abscess in the right flank.

DIFFERENTIAL DIAGNOSIS

DR FAXON The time is short and this case is similar in many respects to the one we have already heard, so I will go through it rapidly

She had colicky pain that came on at night and was severe enough to wake her. In a woman of fifty-six large bowel obstruction is the first thing that comes to mind.

"She vomited small amounts of frothy fluid." Frothy fluid is mentioned again in the history. I can attach no especial significance to it except that each time it is mentioned it is associated with the pain, does not persist, and is not a very striking feature.

The bowel movement seems to have given rather than relieved the pain. If the person was having obstruction, as has been said before, one might expect that an evacuation might well relieve her. In this case she had even more pain, and we think of perforation.

This condition lasted for six weeks, which means that the obstruction must have been partial rather than complete. She had increased constipation, which is to be expected if our diagnosis is correct.

There is no mention in the history of any blood in her stools at this or any other time.

The pain started six weeks before she came in, but one week before she came in she developed a process in the right lower quadrant which was enough to restrict the motion of the leg, was very tender and gave later a high white cell count and temperature.

There was no attempt made to correlate the colicky pain with peristalsis, but certainly from the examination and from the fact that peristalsis was, as noted here, "normal", it would seem that the inflammatory process in the right lower quadrant was a local rather than a general peritonitis, and the obstructive element mechanical rather than inflammatory in origin.

I do not think the mass and the inflammatory process play a part in the edema of the extremities, but think this was due to general conditions of her illness and long-standing sepsis.

She had enough infection to raise her temperature to 101°, and yet the pulse, in a fairly elderly woman, was not over 100.

The white blood cell count was 58,000. That brings us up with a start. Either the count was incorrect, which I suppose I should put down as the last possibility, or else she had some localized shutting down of circulation with resulting gangrene. We might say that the white cell count was due to infection alone, but in an old woman it seems high. Possibly she had some blood disease, but we are given no other information to bear this out.

From the story so far she has had enough

lower abdominal cramps to make me think that an obstruction of the large bowel would have to be well along in the large bowel. I was at tempting to make the cause of the obstruction and the mass in the right lower quadrant one and the same, yet, if it were, she would not have given this x-ray picture and her story would have been different.

"Incision and drainage of a retroperitoneal abscess in the right flank was performed." I wonder if that statement is correct. I wonder whether that might have been a retroperitoneal drainage of an abscess that did not necessarily start retroperitoneally. The question comes up as to whether she had a retroperitoneal mass in the first place causing obstruction from extrinsic pressure on the bowel. I should not think that was likely.

The low red cell count and hemoglobin, it seems to me, can be accounted for either by malignancy or almost equally well on the basis of long-standing chronic sepsis.

To sum up, we know she had diabetes which was under control. We know she was at an age when she would probably show the changes of long-standing severe sepsis and the changes one might expect in a woman of her years. I think that the picture is that of large bowel obstruction with the lesion in the region of the splenic flexure. I picture the situation as being this. She developed obstruction which either perforated into the general peritoneal cavity and walled off, or else perforated retroperitoneally, and thus gave rise to the inflammatory mass in the right lower quadrant. Any such mass in the right lower quadrant certainly by the law of averages should be an appendix that had ruptured. Yet despite what Dr Jones brought out in the other case it seems to me she has had too much crampy pain to suppose this to be a case of an appendix that had ruptured. As to the cause of obstruction in the large bowel, we come down to the two favorites of the day, cancer or diverticulum. The story leaves the left lower quadrant free from symptoms. That should exclude diverticulum, and yet she had no bleeding from the rectum, which one might expect with cancer. I would put my final diagnosis down as obstruction of the large bowel due to diverticulum with perforation in the region of the ascending colon and cecum which went on to abscess formation and was drained retroperitoneally.

I do not know the immediate cause of death, but I think she died from the combination of all she had been through rather than from any terminal event.

DR FRANKLIN G. BALCH, JR. My diagnosis in this case was an abscess in the right lower quadrant of unknown origin. It was obvious where the incision was to be made in this case. A right-sided incision was done, coming down on an inflammatory edematous mass. On exploring further the abscess was found to be retro-

peritoneal, extending up toward the kidney and down behind toward the bladder. As we could not find out where it came from, we put in a drain below and a drain above and closed the wound.

CLINICAL DIAGNOSES

Retroperitoneal abscess
Diabetes

ANATOMIC DIAGNOSES

Adenocarcinoma of the sigmoid with metastases to the heart
Perforation of tumor with large right retroperitoneal abscess
Operative wound, drainage of right retroperitoneal abscess
Necrosis of right psoas and quadratus muscles
Adenomatous polyp of the sigmoid
Cervical polyp
Hemangioma of the liver
Arteriosclerosis, moderate aortic and coronary
(Diabetes mellitus)

PATHOLOGIC DISCUSSION

DR. MALLORY The autopsy showed of course the retroperitoneal abscess which Dr. Balch described. It involved the entire right side of the posterior abdominal wall, going up as far as the kidney and at its lower extremity apparently perforating into the pelvis. There was no generalized peritonitis.

The source of the abscess was at first puzzling until we found a carcinoma of the sigmoid which had ruptured retroperitoneally and the pus had drained around the pelvic brim behind the peritoneum and up on the right side instead of on the left, where one would expect it in a case of rupture of the sigmoid.

A SURGEON Was the cecum perfectly intact?

DR. MALLORY Yes. The appendix was also normal, though it lay in immediate apposition to the pelvic portion of the abscess.

An oddity of the case was the finding of a single metastasis in the heart muscle.

CASE 20262

PRESENTATION OF CASE

First admission A sixty year old Irish janitor entered complaining of a productive cough.

For the past ten or fifteen years he had had colds associated with cough and wheezing during the autumn. These attacks would usually disappear toward Christmas. This condition came on as usual four to six weeks before admission and became worse. It consisted of a rather severe cough with occasional blood streaked material. There was no pain in the

chest. There was some wheezing and some watering of the eyes. During the past year he had become considerably weaker and for the past four weeks had noticed a tightness in the left epigastrium. He had lost ten or fifteen pounds during the past year.

Family history His father was dead, cause unknown. His mother died of pneumonia. There was no family history of tuberculosis, cancer, asthma, hay fever or diabetes.

Marital history He had been married twenty six years. His wife and two children were living and well. There had been no miscarriages.

Past history Twenty-five years before admission he had worked in a gold mine in Australia for a period of four years. During the past few years he had been a janitor. His work consisted in taking care of furnaces among other things. The gas fumes from the furnaces had always aggravated his condition. He did not remember any childhood diseases. He had had some rheumatism and about five years before entry had all of his teeth pulled with some relief. While in Australia he had had typhoid fever. He believed he had some pleurisy on the left side five years ago. This was characterized by pain in the chest with breathing.

Physical examination showed a poorly developed and emaciated man. There were small pea-sized glands in the right axilla and the right epitrochlear and inguinal regions. His chest was flat with a depressed xiphoid. The expansion on the right side was greater than on the left. Throughout both apices there were fine and medium râles, more marked on the left. Throughout both lung fields there were inconstant sibilant râles. At the left apex the breath sounds were bronchial in character. Tactile fremitus and spoken voice were increased. The heart sounds were of good quality. There were no thrills or murmurs. The blood pressure was 128/80. The ankle jerks were absent.

The temperature was 98°, the pulse 60, the respiration 20.

Examination of the urine was negative. Examination of the blood showed a red cell count of 4,450,000 with a hemoglobin of 60 per cent. The white cell count was 6,300, 75 per cent polymorphonuclears, 20 per cent lymphocytes and 5 per cent large mononuclears. The sputum was fluid and showed a few Gram-positive cocci in chains, some elastic tissue and very few cells. No tubercle bacilli were found. One of two stool examinations showed a positive guaiac. The Hinton was negative. The non-protein nitrogen of the blood was 38 milligrams. A tuberculin test of 1:1000 was negative in forty-eight hours.

X-ray examination The upper three fourths of both lung fields showed dense mottled dull-

ness with definite evidence of fibrosis and distortion of the upper mediastinum and of the cardiac shadow, with evidence of thickening of the pleura in the entire right axillary border and the upper half of the left axillary border. The mottled areas in the lungs were quite dense and equal to that of the ribs. No definite cavity was visualized.

He improved somewhat on bed rest and was discharged to the Outpatient Department on the thirteenth day.

History of interval He gained a few pounds for the first month after discharge, but afterwards lost about five pounds. He felt well during the summer, but after the onset of the cold weather his wheezing returned, along with increasing dyspnea and cough. For the past two weeks before his second entry he coughed up about a tablespoonful of gray-white material daily. At the time of readmission he was quite weak. He was seen in the Outpatient Department several times during the interval. His condition in general remained about the same. He entered the Emergency Ward on his own initiative because of weakness and dyspnea.

Second admission, a year and two weeks after his previous discharge.

Physical examination The physical signs in his chest were as follows. The trachea was displaced to the right. There was dullness with increased tactile fremitus and bronchial breath sounds in the right upper lung field. In the left upper lung field tactile fremitus and breath sounds were absent, spoken voice and whispered voice were decreased. The rest of the examination was as at his previous admission.

Laboratory examinations were about the same as at his previous admission.

X-ray showed that there had been a marked change in the appearance of the lung fields since the previous observation. The left lung was now completely collapsed. The right lung was still fibrosed and showed unusually dense markings. There was no evidence of cavity. The density of the right upper lobe was that of the ribs.

Five days after admission 600 cubic centimeters of air was removed from the left chest with some relief. An x-ray film on the following day showed that there had been no re-expansion of the collapsed lung. He rapidly failed, and died ten days after admission.

DIFFERENTIAL DIAGNOSIS

DR DONALD S. KING The summary of the history is that of a man of sixty who twenty-five years ago worked for four years in a gold mine in Australia. Of course we cannot throw out that occupational story. He was apparently well for ten years, then about fifteen years before admission he began to have autumnal attacks of cough with expectoration and wheez-

ing. My allergic training will not allow me to pass by that picture of seasonal asthma. It is of course a common story with a ragweed pollen sensitization, but as we go on with the history I do not believe that we can place much emphasis upon a possible sensitization in this case. The story of repeated attacks in the autumn, clearing by Christmas time, is nevertheless interesting.

He had had pleurisy five years before. The present illness showed weakness, weight loss, cough, sputum, and dyspnea.

Following discharge from the hospital he was better—in fact, almost well—but by the next autumn he again had weakness, dyspnea, and cough and had had some bloody sputum. At the second admission he had the physical signs and x-ray evidence of spontaneous pneumothorax at the left apex.

On the basis of the history, then, of pleurisy, hemoptysis, and spontaneous pneumothorax, our first thought is tuberculosis. The physical signs of moist râles at both apices are consistent with such a diagnosis. The sibilant râles throughout the chest could be explained on this basis.

Laboratory examination, however, does not support the diagnosis of tuberculosis. No tubercle bacilli were found in the sputum. A negative intradermal tuberculin test with a 1:1000 dilution is significant. A test should have been done with a 1:100 dilution, but it would probably have been negative.

I am interested in the report of elastic fibers in the sputum. In these days we have almost forgotten to look for these fibers in a sputum examination. In spite of the record, I doubt their presence in this sputum because a sputum described as fluid and containing almost no cells would rarely if ever contain elastic fibers. If elastic fibers are present it is of course definite evidence of lung destruction such as is present in lung abscess, but under the present conditions I am going to assume that elastic fibers were not present.

The first impression one gets from the x-ray film is of silicosis rather than tuberculosis or other pathological process. Uncomplicated tuberculosis could perhaps give this x-ray picture, but I believe the shadow is too dense to allow of such an interpretation. A malignant process should be considered, but certainly the x-ray picture is not typical of such a process.

On the basis of the occupational history, symptoms, laboratory findings, and x-ray I would then make a diagnosis of silicosis. The particular problem in differential diagnosis is whether we are dealing with silicosis alone or silicosis plus tuberculosis.

The history is a little unusual in that his exposure occurred twenty years before his hospital entrance. He worked for only four years and then had no lung symptoms until many

years later. This is however, not a particularly uncommon story in silicosis with or without tuberculosis. We certainly lack any definite evidence of tuberculosis but the literature reports a number of cases free from tubercle bacilli during life which showed tuberculosis at autopsy. It is true also that many of the men who have reported cases have felt that "massive fibrosis" as shown in the x-ray plate practically always means that there is an associated tuberculosis.

I shall be interested in getting Dr. Alton Pope's reaction on this problem since in his capacity as Director of the Tuberculosis Division in the Massachusetts State Department of Health he has for the past year been engaged in a study of the silicosis problem in Massachusetts with especial reference to the association of silicosis and tuberculosis. I showed him this film yesterday and I believe at that time he felt that the x-ray findings could be explained on the basis of silicosis alone. The problem has become an important industrial one in this State as elsewhere and the special Industrial Disease Commission with which Dr. Pope has been working has presented a two hundred and fifteen page report to the Legislature. The present rates for employers' insurance in the granite and foundry industries are now exorbitant. As I understand it for every one hundred dollars paid in wages ten dollars has now to be paid for insurance. Is that correct, Dr. Pope?

DR ALTON S. POPE. Twelve dollars out of every hundred and a deposit of two hundred dollars to start with.

DR KING. This is a very high insurance rate and the problem is of course of pressing importance.

Another diagnosis which one should consider briefly is malignancy. It is of course interesting that carcinoma of the lung has been said to occur so frequently in miners, but in the two groups reported in the Schneeberg mines and in the mines at Joachimstal the miners were probably working with a radium bearing ore whose effect would be different from that of the gold ore in Australia. In this particular case, however, I see no reason for making a diagnosis of carcinoma.

My diagnosis is silicosis plus tuberculosis, the diagnosis of tuberculosis being added on the law of chances rather than because there is any definite evidence of tuberculosis in this case.

A PHYSICIAN. Is spontaneous pneumothorax apt to occur in straight silicosis cases?

DR KING. I do not think it is common but I have seen cases. A great many cases do have it, but that is usually said to be due to tuberculosis. I shall be very much interested to know whether this was silicosis alone or silicosis and tuberculosis.

DR TRACY B. MALLORY. Dr. Pope, have you anything to add?

DR POPE. I think I have very little to add to

what Dr. King has said. Unfortunately I missed the first part of the history.

The negative tuberculin is I think very important in this case. Of course if it were tuberculosis and silicosis though, it would be entirely possible to have a negative test with as advanced a stage of the disease as this apparently is.

I think the roentgenological findings are consistent probably with either advanced silicosis or advanced silicosis with tuberculosis. It is extremely difficult in some of these cases with so much involvement to say we have a superimposed tuberculosis.

The history in regard to the length of time between exposure to silica dust and the development of the disease is not unusual in silicosis. I remember particularly a case I saw in the Outpatient Department, a sand blaster in Lynn. He left there in 1919 and worked as a truck farmer. In 1922 he came into the hospital with far advanced silicosis and tuberculosis. The symptoms dated a year before he came in here.

I agree with Dr. King that the case under discussion to day is advanced silicosis, probably complicated with tuberculosis but I think we shall have to rely on the autopsy in regard to the last point.

DR KING. I might show you an x-ray film of another case that was proved to be silicosis and tuberculosis. The x-ray appearance in this case is somewhat different from the one we have been discussing and there is unquestionably a large cavity present which looks like tuberculosis. The sputum was full of tubercle bacilli and the patient died of hemorrhage.

DR J. H. MEANS. I should like to ask Dr. King or Dr. Pope whether the increasing number of judgments in favor of employees have forced employers to take any better precautions against the development of silicosis or to diminish the exposure to silica dust in the workrooms.

DR KING. Dr. Pope has had much more experience along that line and can answer the question far better than I.

DR POPE. Two or three years ago one firm in Massachusetts had a consultation with Dr. Drinker, and under his direction has installed a dust removal system that has given very satisfactory results. This is the only granite plant in the State that has a really effective exhaust system. Most firms have installed exhausts on their surface-cutters as required, but on inspection it was often found that the dust was discharged where it was carried back into the shed. In Quincy most of the firms have dropped compensation insurance, and are running the risk of suits at common law.

It is only in the past two or three years that the hazard from silicosis in foundries has been generally recognized. In our examination of

some 1,600 foundry workers we found about 9 per cent had evidence of silicosis alone and an additional 25 per cent silicosis complicated with tuberculosis. That is about one-half the frequency of silicosis and tuberculosis found in granite workers.

CLINICAL DIAGNOSIS (FROM HOSPITAL RECORD)

Silicosis

ANATOMIO DIAGNOSES

Silicosis

Pulmonary emphysema

Pneumothorax, left

Pulmonary collapse, partial, left

PATHOLOGIO DISCUSSION

DR MALLORY The autopsy on this man showed, so far as I have been able to make out, pure silicosis. I have the lungs here and I will pass them around. The major portion of his upper lobes and a very large portion of both lower lobes were absolutely atelectatic, and of a firmness which varies from that of shoe leather almost up to rock. It is extraordinarily dense material. In some places, for instance at this apex, there is hardly an alveolus left—perfectly solid tissue. In the remaining portions of the lung, as one would expect, there is a well-marked emphysema. The persisting alveoli for the most part are dilated up to three, five or ten times the normal size.

A SURGEON Did you find the rupture that caused the spontaneous pneumothorax?

DR MALLORY We did not. There were innumerable emphysematous blebs, from any one of which it could have occurred. At the time of autopsy the pneumothorax had practically resolved.

I will take a minute to show the sections. These pink whorls of dense fibrous tissue are very characteristic of silicosis, and as I move the slide around you can see how densely they are packed. They lie almost invariably in interlobular septa in the early stage, one can trace out the lymphatics of the lungs very accurately by the presence of these nodules in and around them. In between these areas there is an extreme degree of emphysematous dilatation of the

alveoli. Besides the silicosis there is a distinctly more marked degree of anthracosis than usual, possibly related to his terminal period as a janitor.

The blood vessels throughout the lung, but particularly in the neighborhood of the most involved areas, show extreme degrees of intimal thickening. Here is one artery in which less than one fifth of the lumen is still patent.

DR KING Do you think he had elastic fibers in his sputum?

DR MALLORY I doubt it very much. There is no active destruction of lung tissue going on anywhere.

DR MEANS I should like to ask whether his vital capacity was ever determined.

A HOUSE OFFICER No, sir.

DR MEANS I think vital capacity ought to be measured in cases of this kind, because it is a quantitative measure that throws some light on the degree of limitation of an important function.

DR MALLORY My impression at autopsy was that one could hardly get a lower vital capacity than this man would have shown.

DR MEANS Dr McCann of Rochester is attempting to work out a ratio between residual air, which can be measured without too much difficulty, and vital capacity, in silicosis, because he believes that an index may be obtainable which will be useful in an objective way for determining the degree of limitation, evidence that will be valuable when these cases come up in court.

A STUDENT How often do you get hemoptysis with silicosis?

DR MALLORY Perhaps Dr Pope will answer that.

DR POPE I do not know. We do get cases, but we examine men who are actually working. Few give histories of hemoptysis.

DR MALLORY One rather interesting thing is that with this tremendous pulmonary involvement, fibrosis in some areas, emphysema everywhere else, and marked pulmonary arterio-sclerosis, his heart weighed only 250 grams and the right ventricular wall measured only 6 millimeters in thickness. That was proportionately a little high perhaps for so small a heart, but would certainly not justify the diagnosis of cor pulmonale.

THE ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

ONE of the interesting and informative publications of the year is that of the Proceedings of the Annual Congress on Medical Education, Licensure and Hospitals. It should be carefully read by those who are interested in the purposes of the several organizations taking part in this Congress.

As for medical education, great changes have taken place, first, in the elimination of most of the commercial medical schools in existence at the beginning of the present century, secondly, in the consolidation of some weaker schools, and thirdly, in the establishment of classifications of all of the institutions engaged in teaching medicine. It is thereby apparent from the report of Dr. Ray Lyman Wilbur that there has been insufficient progress in bringing a considerable proportion of medical schools up to satisfactory standards in that there is a great

disparity in the quality of teaching even in the Class A schools. This seems to be as great as the difference in quality which existed in a comparison of the Class A and Class C schools at the time of the early classification of these institutions.

Dr. Wilbur contends that the time has come when the lower grade A schools should not stand on a statistical parity with those of higher rank and that one imperative problem is to bring the now doubtful Class A schools up to equal standing with those in the higher level, for it is apparent that the finished products of our medical schools should stand on a practical level of excellence. The intimation expressed by Dr. Wilbur is that the laboratory made the medical schools improve the quality of instruction just as scientific medicine has raised the average quality of medical practice.

Fortunately there is an abundance of good medical education and some weak and struggling schools should either be made to develop adequate teaching methods or cease to function.

The demand of the present age is to provide the country with competent administrators of the art of medical practice.

The establishment of standards on paper will not be effective unless the several states confer on the administrators of the statutes authority to enact laws which will compel medical schools to improve their curricula so that they will conform to the recommendations of the Council on Medical Education and Hospitals. While the majority of the states may adopt the recommendations of the Council, the indisposition of some legislatures to confer the requisite power on departments of education or boards of registration to inspect medical schools, with authority to act, will prevent the general adoption of the standards of the Council.

The difficulty lies in the indifference of the people with respect to the questions involved and the remedy depends on an aroused public understanding of the advantages of scientific medicine which will impress the legislatures with the wisdom of better standards.

Efforts in this direction in some sections have not been effective and other methods than those now employed seem to be necessary. In order to overcome legislative inertia a well-planned campaign must be conducted. In so far as the medical profession is responsible for this legislative apathy in Massachusetts, the *Journal* suggests that the deans of our Class A medical schools appeal to their graduates to unite under the leadership of the Massachusetts Medical Society Committee on Legislation in an effort to instruct the members of the General Court on the economic importance of the administration of the health problems of the state through a higher average of practitioners. Standards of

practice depend on the finished product of medical schools to a large degree. Can the Committee on Legislation feel sure of the united support of graduates of Class A medical schools? It has not been in evidence hitherto.

INCREASED HOSPITAL BEDS FOR TUBERCULOSIS

A THREE-YEAR survey of tuberculosis sanatoria throughout the United States just completed by The National Tuberculosis Association, reveals that general hospitals are opening their doors to tuberculosis cases, increasing facilities are being provided for the care of tuberculous children, and 6,863 new beds for treatment of the disease have been added to the nation's public health armament despite the depression.

These data which have been compiled in the form of a sanatorium directory listing facts about 659 institutions containing a total of 86,917 beds, show that there are now available in the United States, 64 federal institutions containing 11,431 beds, 357 state, county and municipal institutions containing 56,940 beds, 73 private institutions containing 4,344 beds, and 165 semi-private institutions containing 14,202 beds.

According to Dr. Kendall Emerson, Managing Director of the National Tuberculosis Association, the significant aspects of the study are the increase noted in the provision made for children in sanatoria throughout the country and the increasing number of general hospitals that are admitting tuberculous patients. Thus, in Idaho, as a substitute for a state sanatorium, provision has been made to care for tuberculous patients in properly equipped units of two general hospitals, general hospitals are being used extensively to provide beds for terminal and convalescent cases in Detroit, and Chicago, Cleveland, and Philadelphia have opened hospitals for convalescent cases.

This change in attitude has been brought about partly by the increasing use of chest surgery in the treatment of tuberculosis.

THE APPOINTMENT OF DR. OVERHOLSER

GOVERNOR Ely nominated Dr. Winfred Overholser to the position of Commissioner of Mental Diseases, and the Council under suspension of the rules confirmed the action of the Governor.

The opportunity for this appointment came with the resignation of Dr. James V. May, who wished to return to his former position of Superintendent of Boston State Hospital. Dr. May's administration as Commissioner was a noteworthy continuation of the policies which

have added to the prestige of Massachusetts in the care of the mentally ill.

Dr. Overholser has been advanced from the position of Deputy Commissioner and is well equipped to take full charge of this next to the largest department of the state. Its importance consists in the oversight of sixteen institutions dealing with mental diseases, and twenty-one private hospitals. The personnel in this department includes one hundred and eighty physicians, all of outstanding ability, and about five thousand other employees. In addition to an annual expenditure of about eight millions, about seven millions are in progress under the P. W. A., and expansions in various ways.

Even with these large expenditures the several state institutions are overcrowded but according to statements accredited to Dr. Overholser, this is not because mental diseases are increasing. It may fairly be assumed that Massachusetts is trying to care for all cases which may need institutional treatment. Dr. Overholser has the benefit of a previous liberal and professional education and long experience in the field of mental diseases.

One especially important characteristic of Dr. Overholser is his desire to cultivate, among the family physicians, more interest in psychiatry, because here, as in other fields of medicine, the opportunity to seek for prevention and early treatment should be recognized by the general practitioner.

The appointment is highly creditable, and Massachusetts may look forward to progress in dealing with the problems of mental disorders.

MISCELLANY

DR. HARVEY ELECTED PRESIDENT OF THE ASSOCIATION OF YALE ALUMNI IN MEDICINE

At the annual meeting of the Association of the Yale Alumni in Medicine Dr. Samuel C. Harvey was elected President. Dr. Harvey has held the position of Professor of Surgery at the Yale School of Medicine for several years.

THE RABIES DANGER

Dr. Myron H. Davis of the Saugus Board of Health has asked the Selectmen to issue an order for the restraint of dogs in that town. An unusual number of dog bite cases have been reported in that section of the state and two deaths apparently caused by rabies have occurred. The second case will be studied by the pathologist at the Boston Children's Hospital in order to determine whether death was due to rabies.

THE BOSTON FLOATING HOSPITAL HAS A DEFICIT

The report of the Boston Floating Hospital for 1933 presents the following facts: 13,049 days of care, 1370 new patients, 938 operations, and 1111

visits made by the field nurse. The total income was \$75,219.30 with a total expense of \$79,346.70, thus leaving a deficit of \$4,127.40. This deficit must be raised by contributions and merits a generous response.

This is one of the important charities of interest to Boston.

UNNECESSARY DEATHS

According to the *New York Times*, Health Commissioner Parran has said that of the yearly toll of one hundred and fifty thousand deaths in New York State, more than fifty thousand die for lack of adequate medical treatment.

This spectacular statement is too indefinite to warrant more than a question as to whether the Commissioner has facts at his disposal to sustain this alarming claim.

It is, however, generally believed that a great many lives are being needlessly sacrificed, but we dislike to think that medical service is denied to so large a number, and if so the contributory factor may be in large measure due to the ignorance and prejudice of these people who procrastinate or worship false gods. It cannot all be laid to the medical profession. One does not see the remedy for the great mortality until the facts are shown. It would seem probable that enlightenment of the masses would accomplish some good, and setting the medical profession at work to find ways to supply needed treatment is indicated. If state medicine is required to meet this challenge, even that is a lesser disquieting procedure than this great human loss.

If the profession cannot cope with this problem, the people will, and if the electorate gets aroused, there may be swift and unwise action.

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MAY, 1934

Lobar pneumonia and pulmonary tuberculosis show a slight increase over last year's figure.

The unusually high incidence of measles of the past few months is definitely subsiding.

Typhoid fever and diphtheria continue to be reported in diminishing figures.

Anterior poliomyelitis, epidemic cerebrospinal meningitis, chicken pox, mumps, German measles, scarlet fever, and tuberculosis, other forms show nothing remarkable.

Whooping cough and dog bite show considerable increase over the corresponding month of last year.

RARE DISEASES

Anterior poliomyelitis was reported from Cambridge 1, Quincy 1, Walpole 1, Wrentham 1, total 4.

Dysentery (amebic) was reported from Worcester 3.

Dysentery (bacillary) was reported from Boston 2.

Encephalitis lethargica was reported from Boston, 1, Clinton 1, Deerfield 1, total 3.

practice depend on the finished product of medical schools to a large degree. Can the Committee on Legislation feel sure of the united support of graduates of Class A medical schools? It has not been in evidence hitherto.

INCREASED HOSPITAL BEDS FOR TUBERCULOSIS

A THREE-YEAR survey of tuberculosis sanatoria throughout the United States just completed by The National Tuberculosis Association, reveals that general hospitals are opening their doors to tuberculosis cases, increasing facilities are being provided for the care of tuberculous children, and 6,863 new beds for treatment of the disease have been added to the nation's public health armament despite the depression.

These data which have been compiled in the form of a sanatorium directory listing facts about 659 institutions containing a total of 86,917 beds, show that there are now available in the United States, 64 federal institutions containing 11,431 beds, 357 state, county and municipal institutions containing 56,940 beds, 73 private institutions containing 4,344 beds, and 165 semi-private institutions containing 14,202 beds.

According to Dr Kendall Emerson, Managing Director of the National Tuberculosis Association, the significant aspects of the study are the increase noted in the provision made for children in sanatoria throughout the country and the increasing number of general hospitals that are admitting tuberculous patients. Thus, in Idaho, as a substitute for a state sanatorium, provision has been made to care for tuberculous patients in properly equipped units of two general hospitals, general hospitals are being used extensively to provide beds for terminal and convalescent cases in Detroit, and Chicago, Cleveland, and Philadelphia have opened hospitals for convalescent cases.

This change in attitude has been brought about partly by the increasing use of chest surgery in the treatment of tuberculosis.

THE APPOINTMENT OF DR OVERHOLSER

GOVERNOR Ely nominated Dr Winfred Overholser to the position of Commissioner of Mental Diseases, and the Council under suspension of the rules confirmed the action of the Governor.

The opportunity for this appointment came with the resignation of Dr James V May, who wished to return to his former position of Superintendent of Boston State Hospital. Dr May's administration as Commissioner was a noteworthy continuation of the policies which

have added to the prestige of Massachusetts in the care of the mentally ill.

Dr Overholser has been advanced from the position of Deputy Commissioner and is well equipped to take full charge of this next to the largest department of the state. Its importance consists in the oversight of sixteen institutions dealing with mental diseases, and twenty-one private hospitals. The personnel in this department includes one hundred and eighty physicians, all of outstanding ability, and about five thousand other employees. In addition to an annual expenditure of about eight millions, about seven millions are in progress under the P. W. A., and expansions in various ways.

Even with these large expenditures the several state institutions are overcrowded but according to statements accredited to Dr Overholser, this is not because mental diseases are increasing. It may fairly be assumed that Massachusetts is trying to care for all cases which may need institutional treatment. Dr Overholser has the benefit of a previous liberal and professional education and long experience in the field of mental diseases.

One especially important characteristic of Dr Overholser is his desire to cultivate, among the family physicians, more interest in psychiatry, because here, as in other fields of medicine, the opportunity to seek for prevention and early treatment should be recognized by the general practitioner.

The appointment is highly creditable and Massachusetts may look forward to progress in dealing with the problems of mental disorders.

*Average number of cases for May during the preceding five years

A REPORT OF THE MILBANK MEMORIAL FUND

The number of physicians' calls to sick working people was cut by one-sixth during the period 1929 to 1933 while the percentage of illnesses hospitalized increased considerably during the same period, and the amount of free care both from hospitals and physicians soared to a very high point, according to a first hand census to determine the relation between sickness and the depression made jointly by the United States Public Health Service and the Milbank Memorial Fund

The report presenting these comparisons has been drawn up by G. St. J. Perrott and Selwyn D. Collins of the Public Health Service and Edgar Syden

stricker, director of public health activities of the Milbank Memorial Fund. It is one of a series of reports several of which have already been made public

The survey consisted of a house-to-house canvass of 6,686 wage-earning families comprising 29,000 individuals, residing in Baltimore, Birmingham, Cleveland, Detroit, New York, Pittsburgh, and Syracuse. After the investigators had turned in their findings, the families were classified into three groups, namely, "Poor," comprising those with an annual income averaging less than \$150 per person, "moderate" those with \$150 to \$424 per person and "comfortable," those with \$425 or more per person per year. Families with downward shifts in income since 1929 from one class to another were compared with families who experienced no loss of income. As a check these results were also compared with findings for families in similar income levels by the Committee on the Costs of Medical Care for the period 1928-1931, and it is indicated that only about 52 per cent of the cases of illness received some medical care, whether from doctor or hospital, in 1933 as against 68 per cent in 1928-1931, the difference amounting to a drop of 23½ per cent. However, hospitalization taken by itself showed a rise of about 14 per cent for this period, being given to about 74 per cent of the illnesses in 1933 as against 6½ per cent in 1928-1931.

Figuring on the basis of physicians' calls per thousand persons (whether sick or not), the survey shows nearly 11 per cent fewer calls in 1933 for all the families questioned than would presumably have been the case if none of them had experienced a loss of income since 1929. In other words, this is the drop in doctors' care as shown by comparing the families whose incomes dropped with those who remained on their respective wage levels. But the sickness rate among families with reduced incomes was higher than that of the families not suffering loss of income and this brought a need for more physicians' care. When this fact is taken into account, the physicians' calls actually made were 17 per cent fewer than would have been expected if the ability to purchase medical care had not been lowered. Nearly 29 per cent more hospital care per thousand persons (whether sick or not) was shown in 1933 than would have been the case if all the families had continued without reduction of income.

Along with the cut in general medical care and the increase in hospitalization went increases in the amount of free care obtained. The comparisons reveal that the families investigated in the seven cities received 49 per cent more free hospital care than they would have received if there had been no depression. About 15 per cent more free care was obtained from physicians.

An interesting fact revealed by the survey was that families whose incomes had been in the poor class since before 1929 got considerably more free care than the wage-earning families who had

dropped from higher income levels. Thus the wage earners who remained 'poor' paid for only 24 per cent of the calls made by doctors, while those who had dropped from the 'moderate' group to the 'poor' group paid for 42 per cent of the calls received and those who had been comfortable but are now 'poor' paid for a still higher proportion 46 per cent of the doctors calls which they received. Taking the new 'poor' and the 'chronic poor' all together it was found that 61 per cent of the calls made by physicians were free to the families.

There were more acute disabling illnesses in the

poor class than in the "comfortable" class, the rate for the former being 108 cases per 1,000 persons or slightly more than one in ten as against a corresponding figure of 80 per 1,000 persons in the comfortable class. However the poor received only 2.2 calls per illness from doctors as compared with 3.7 calls for the "comfortable." This difference in physicians care presumably arose through better ability to pay on the part of those with the higher incomes. The poor however received more hospital care per case and more care from visiting nurses than those rated as 'comfortable'.

NOTES

The material presented in this month's bulletin represents the author's own conclusions regarding the subject of his article, Radiosensitivity of Tumors which first appeared in the *Archives of Surgery*, December, 1933

The article has been made easily available in monograph form. Copies may be obtained (price twenty-five cents) by addressing the American Society for the Control of Cancer, 1250 Sixth Avenue, New York City

RADIOSENSITIVITY OF TUMORS

BY FRED W STEWART, M.D

Conclusions of the Author

"My purpose has been to emphasize the complexity of the problem of radiosensitivity. I have called attention to the difficulties of establishing hard and fast rules. I have encouraged the notion that ideas of tumor sensitivity may change with changes in radiologic technic. I have called attention to the need of expressing response to radiation in terms of dosage. Peculiarities in the behavior of certain tumor types have been noted, and differences in the responses of apparently similar tumors in different regions have been discussed. Much of the paper has unfortunately been devoted to the statement of observed facts, which are wholly unexplained. It is difficult to summarize in a few sentences material which many pages have but incompletely described, yet since some crystallization is necessary, the following brief paragraphs may serve

"1 Radiology is an active science. Ideas and methods are constantly changing. As methods change, notions of what may be expected from irradiation of tumors will also change. For example, if current ideas of radiosensitivity were derived wholly from observations made in the days when the low voltage x-rays represented the entire therapeutic armamentarium, then sensitive tumors would be rare and the field of radiology limited. Improved methods, while they alter no fundamental principles, constantly widen their applicability to the advantage of the patient with cancer.

"2 Radiosensitivity may mean rapid tumor regression, slower progressive regressions over a period of from days to weeks or slow chronic atrophy requiring months or perhaps a year for completion. Of course, the same mechanisms are not responsible for these various responses, nor do they occur in the same types of tumors. Radiosensitivity does not mean the certainty of cure by irradiation, nor does radioresistance imply that a given tumor is not curable by irradiation.

"3 Certain tumors seem to possess inherent properties of radioresistance, as witnessed, for example, in the melanomas and neurogenic tumors

"4 Radiosensitivity increases with increasing embryonal quality of the tumor cells. By embryonal quality I do not imply that all tumors of embryonal origin are equally radiosensitive, since embryonal quality I do not imply that all tumors of embryonal tumors rapidly acquire adult characteristics, for example, the complex teratomas.

"5 Radiosensitivity increases with the increasing degree of anaplasia. This rule is subject to interpretation, for not all anaplastic tumors are radiosensitive. Some are highly resistant, and unless the exact type of anaplastic tumor is specified, anaplasia may be of little significance.

"6 Radiosensitivity is always a relative property. When one states that a carcinoma of the breast, for example, is radiosensitive, one should imply that it is sensitive according to the accustomed scale of behavior of tumors of the breast and not according to the same scale of sensitivity one applies to lymphosarcoma.

"7 Tumors are apt to be more sensitive in young subjects. An anemic or cachectic person is a poor subject for radiation.

"8 Infection interferes with a normal response to radiation.

"9 Desmoplastic tumors are apt to be radioresistant.

"10 The tumor bed is of great importance. A normal tumor bed is generally favorable. Bone cartilage and fat make unfavorable mediums for reactive processes and hence for regression of the tumor. An avascular bed is unfavorable for response to radiation.

"11 Tumors, when metastatic to lymph nodes, may be more or less sensitive than the primary tumors. This phenomenon is not fully explained. Metastases to the lymph nodes, long established, tend to be less sensitive than recent emboli. The old metastasis has had time to acquire its definitive blood supply and to adapt itself to its new surroundings, while the recent embolus is still foreign to its new soil. A recent, rapidly growing metastasis is more apt to be unstable than a smaller metastasis of longer duration. Cystic nodes are apt to be resistant.

"12 Bulky tumors may become resistant after infarction and liquefaction, even though they belong to the usually sensitive types. This may be due to the fact that fibrosis proceeds slowly and inefficiently under such conditions. The cells in the liquefied areas are removed from restraining fibrosis. The same explanation may be applied to the resistance of tumor cells lying in the midst of degenerative or secretory mucin, for example in gelatinous carcinomas, mucinous ovarian adenocystomas, degenerating chondroblastic tumors or Schneiderian cancer with an overproduction of mucus. Secretion, however, is the expression of the assumption of adult character in a tumor cell and hence must supposedly render it more resistant.

"13 The anatomic characteristics are of decided

importance Among these may be mentioned the papillary character, delicacy of the blood supply and enclosure within a firm capsule, which may result in the obliteration of circulation after irradiation has caused the tumor to become edematous. Diffuse lymphatic plugging by tumor cells may lead to edema and interference with cell fluid exchanges.

14 In the case of certain tumors some unknown physiologic mechanism seems involved in the response to radiation. Examples of this appear in myoma uteri and carcinomas of the breast, ovary and thyroid.

15 The effect of radiation is always complex. It involves not only the tumor cell, but the tissues of the host, and possibly general reactions on the part of the host. The ultimate effect of the radiation must always result from a nice balance between tumor effect and response of the host tissue.

The relative importance of the two mechanisms varies in different tumors. In some instances the known sensitivity is such that the radiologist may endeavor to destroy the tumor cells. In others he can but hope for restraint of growth by moderately affecting the tumor cell and trusting that the responses of the host tissue will play a decided rôle. Under such circumstances tumor cells may remain in an indolent state in the midst of fibrous tissue for many years without giving rise to further damage.

16 Unfortunately more particularly in the case of the extremely sensitive tumors the radiologist is apt to be so impressed with the initial regression of the disease that he fails to push his treatment to tolerance and waits until, after a period of quiescence, the disease recurs in a more resistant form when he must essay to do under poorer conditions what he failed to do at the start."

HISTORICAL SKETCHES ON PUBLIC HEALTH PREPARED FOR THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH AND SPONSORED BY THE MASSACHUSETTS MEDICAL SOCIETY

VACCINATION OF TODAY

BY ELEANOR J. MACDONALD, A.B.*

It is hard for those of us who live in such a community as is the Massachusetts of to-day, to imagine the havoc wrought by smallpox in the past. This disease which in its virulent form may kill as high as one out of every four that it attacks exerted a tremendous influence on the civilization of former centuries. So rarely did a person escape the disease that it was said with some justice, that no one should count a family until all of the children had had smallpox. Lord Macaulay in his History of England, writing of the time of William and Mary, makes this interesting comment: That disease over which science has since achieved a succession of glorious

and beneficent victories, was then the most terrible of all the ministers of death. The havoc of the plague had been far more rapid but the plague had visited our shores only once or twice within living memory and the smallpox was always present, filling the churchyard with corpses, tormenting with constant fears all whom it had not yet stricken, leaving on those whose lives it spared the hideous traces of its power, turning the babe into a changeling at which the mother shuddered, and making the eyes and cheeks of the betrothed maiden objects of horror to the lover.

In 1720 in Boston, 10 per cent of the population was killed by smallpox in one year. In 1933 there was not a single case of smallpox in Massachusetts. The intervening history has contained much that was detrimental and deterrent to the present state of smallpox. At first those who opposed vaccination had grotesque pictures displayed portraying the development of horns and hoofs on those who had submitted. These pictures appeared not in jest, but as the sincere convictions of those who foresaw in vaccination all sorts of imaginary dangers. Time has shown the fallacy of such notions, yet many of the quotations being used today as arguments against vaccination originated in this epoch.

The vaccinations that were performed in the troublous times of Dr. Waterhouse were made directly from the arm of one person to the arm of another. Those were the days before we had acquired our present-day knowledge of aseptic precautions. With such a procedure of transfer from one person to another commonly without adequate knowledge of the disease or even several diseases from which the original person might be suffering, it was to be expected that occasional ill effects should occur. Sanitary precautions were ignored in the various steps leading to and including vaccination. The fear of smallpox was so great that frequently the doctor was not content with a single vaccination, but applied several in different parts of the body to insure a higher level of resistance.

During the second half of the last century and especially during the twentieth century there have been great strides made in the method of vaccination. The development of our knowledge of bacteriology and the discoveries resulting from the scientific studies made of the subject are responsible for this. No longer is the vaccine introduced directly from the arm of one person to the arm of another. All the material is carefully produced in well supervised laboratories under precautions which would do credit to the operating room of any hospital. The material is carefully tested and standardized and before release is further tested by the Federal Government. It is placed in sealed tubes under the most careful precautions and these tubes are kept sealed until opened by the physician who is to vaccinate. No longer do we see the severe and usually painful scratching at the point where the vaccine is to be

*Statistician, Division of Adult Hygiene, Massachusetts Department of Public Health.

introduced A successful vaccination can be performed by so slight a pricking of the skin with a sterile needle as not even to draw blood

From the foregoing account of vaccination to-day and yesterday one can see how manifestly unfair it is to compare them,—and yet, much of the opposition does originate from an exclusive consideration of the earlier type of vaccination.

The results of vaccination have been so striking that they need little if any, comment Massachusetts, which enjoys the protection of a law requiring vaccination of children attending the public schools, has the lowest smallpox rate of any state in the Union Those states that do not have compulsory vaccination have from twenty to two hundred cases of smallpox for every case that occurs in Massachusetts

A group of states which have laws that forbid compulsory vaccination have 115 cases of smallpox for every case that Massachusetts has, and yet there are those who, like the fear-ridden or uninformed of the eighteenth century, would amend our laws and place us in the position of having 115 times as much smallpox as we now have This they do while impugning the integrity of those who defend vaccination on its proved merits This they do by defaming those who have given so unsparingly of their time and energies to the perfection of this life-saving procedure and to support their arguments they quote from the untoward results leading to the comparatively few deaths from inoculation in the past centuries Just so long as Massachusetts continues to enjoy compulsory vaccination will it also enjoy its freedom from smallpox If, however, the compulsory vaccination law is withdrawn, then the penalty of increased suffering and death from smallpox, now the lot of other states who have followed false prophets, will become the lot of Massachusetts It is unlikely that such a condition will ever exist here, however Because in spite of the vigorous propaganda carried on by the opponents of scientific medicine, the public at large realizes to-day the debt of gratitude that it owes to Dr Jenner and respects his memory for the contribution that he made

POSTGRADUATE COURSES

TUFTS COLLEGE MEDICAL SCHOOL
416 Huntington Avenue Boston Mass

Office of the Dean, June 21 1934

Editor *New England Journal of Medicine*

Inquiries from our graduates have prompted us to consider the offering of postgraduate courses to

physicians A course in Internal Medicine for General Practitioners has already been announced in your advertising columns This course will be given during July at the Beth Israel Hospital The tuition fee is fifty dollars Further information regarding it may be had by applying to Dr Harry Linenthal Physician in Chief of the Beth Israel Hospital

Similar courses may be made available at the Boston Dispensary and the Boston City Hospital during August if applicants therefor are interested It is possible that many of the clinical facilities of Tufts Medical School could be placed at the disposal of practicing physicians in New England and it is the desire of the School to thus utilize them whenever suitable

I hope you can call this to the attention of your readers Physicians interested may communicate with the Committee on Postgraduate Courses at Tufts College Medical School, 416 Huntington Avenue, Boston Massachusetts

Very truly yours

A WARREN STEARNS, M D, Dean

PRE-PARALYTIC INFANTILE PARALYSIS SERVICE

THE COMMONWEALTH OF MASSACHUSETTS

Department of Public Health

State House Boston, June 20 1934

Editor, *New England Journal of Medicine*

May I announce through your columns that beginning July 1, 1934 the Department will resume twenty-four hour telephone service to enable physicians to obtain consultant service in cases of suspected pre-paralytic infantile paralysis All calls during office hours should be made directly to the State House, Capitol 4600 at other hours all such calls will be handled through Kenmore 8100

It is the purpose of this consultant service to assist physicians in suspected pre-paralytic cases in which serum treatment may depend upon prompt diagnosis The Department, cannot, however, offer any such service in paralyzed cases and will be forced to refuse to send a consultant in such instances As for the past two years serum may be obtained directly from certain local hospitals, providing a lumbar puncture has already been performed and examination of the fluid shows indications of infantile paralysis

Very truly yours

HENRY D CHADWICK M D

Commissioner of Public Health

THE AMERICAN NEISSERIAN MEDICAL SOCIETY

Boston June 20 1934

Editor, *New England Journal of Medicine*

A group of physicians from various sections of the country met together at Cleveland Ohio on June 12 1934 and formed an organization for the purpose of doing on a national scale the work

rted in 1930 by the Neisserian Medical Society, Massachusetts. The name of the organization is the American Neisserian Medical Society. The following officers were elected: Dr J. Deane Barney of Boston, president; Dr P. S. Pelouze of Philadelphia, vice-president; and the undersigned, secretary.

Membership is limited to neurologists and gynecologists especially interested in and who desire to work for improvement in the management of gonorrhea.

The Massachusetts Society will continue to function as an independent organization but will cooperate in every possible way with the National Society.

Very truly yours,
OSCAR F. COX, JR., M.D.

THE PERIODIC HEALTH EXAMINATION

Editor *New England Journal of Medicine*

Having been interested for some years in the principle of periodic health examinations and having come to believe that the principle is sound, I read with interest the opinions published on this subject by the Committee on Public Health of the Massachusetts Medical Society.* The Committee says in its concluding paragraph that 'universal investigation of recently acquired trivial signs and symptoms by the family doctor would be more profitable than the periodic health examination.'

This may be true, but the proposal has serious disadvantages. First, few actively occupied persons can be induced to consult a physician for symptoms which, to them, appear trivial. Secondly, those having neurotic tendencies would inevitably be stimulated to watch their symptoms still more closely and, finally, if the plan were followed generally, much additional expense would be incurred for needless visits to the physicians.

On the other hand, it is certainly the duty of the family physician in the present and in the future to do far more toward the promotion of health in the positive sense and toward the prevention of disease than has been customary in the past. The periodic examination conducted intelligently by the family physician who knows the background of the patient's life and who understands his personality should offer valuable opportunities which would otherwise be missed. For example, dangerous diseases such as pulmonary tuberculosis, incipient circulatory weakness, ulcer of the stomach, and cancer might be detected earlier. Maladjustments too which have begun to cause neurosis or which are laying the foundation for a nervous breakdown could be promptly recognized, and persons of middle age should be cautioned about overweight. These are but a few examples of what might be accomplished. I believe that periodic examinations made by the family

physician are more likely to be useful than those performed by persons who do not really know the people whom they examine.

No plan of medical supervision that can be devised now will detect all cases of internal cancer in an early stage or prevent certain other dangerous diseases which we do not know how to prevent. But should the periodic examination, therefore, be condemned?

Most of us have long since become accustomed to see our dentist frequently in order that small cavities may receive prompt attention. The practice is becoming general of consulting the pediatricist about the growing child even when all seems well with it. Moreover, public school children are being examined at regular intervals and many universities have undertaken periodic examinations of their student body. If these things are worth while, should we not continue to make medical checkups during the later years of adult life? There is no period of life during which health may not be jeopardized. The active working years bring increased responsibility for the welfare of others, and render positive health of the greatest importance. Is this the time to give up medical supervision?

As for the examination itself, a simple routine should be carried through at every examination and this need be supplemented only when there are indications for so doing. The expense to the patient would then, usually, be small. For those who have shown no serious signs or symptoms, an annual examination would be reasonably adequate. The physician, however, should use his best judgment in every case and should advise certain patients to return at shorter intervals.

The periodic examination has certain great advantages for the patient. It enables him without loss of self-respect to consult his physician about apparently trivial symptoms of which he would be ashamed to complain, and the advice given should, frequently, enable him to improve his health and thus to increase his efficiency and enjoyment of life.

Should the principle of the periodic examination receive general acceptance by the medical profession, it would become necessary to convince the public of the value of this procedure. The public should be told the limitations as well as the advantages of the plan, but should organized medicine undertake to initiate the plan, it would lay itself open to the suspicion of advocating it to increase business. For the same reason, it might at first be embarrassing for the family physician to advocate periodic examinations. Therefore, the potential value of the periodic examination should first be explained to the public by official health agencies and by lay groups which are interested in the promotion of health. Medical societies and physicians who believe in the value of such examinations should then help to popularize the movement.

GEORGE CHEEVER SHATTUCK, M.D.

OBITUARY

DR ABNER POST

1844—1934

Abner Post was born in Westfield Massachusetts, August 9 1844 He died in Cambridge, Massachusetts, April 20, 1934 At the age of twelve his father died and the boy with his mother, went to live with her father Those early years, spent in his grandfather's household, made a lasting impression on his character

He prepared for College at Williston Academy, and graduated from Yale in 1866, and received his M D from Harvard four years later He served as a surgical house pupil at the Massachusetts General Hospital under Doctors Richard Manning Hodges and Henry J Bigelow He studied abroad for two years mostly in Vienna, and on his return to Boston entered the U S Marine Hospital at Chelsea, where he gained a wide experience in the treatment of venereal diseases as well as general medical and surgical work

In 1876 he was appointed to the Staff of the Boston Dispensary and continued on active duty there until he retired December 31 1913

Dr Post had great interest in Surgery and would doubtless have devoted his life to this field had he not yielded to the influence of Dr Francis B Greenough a dermatologist and syphilographer of note with whom he became associated at the Dispensary, and who revived his interest in syphilis In consequence he gave up his position as surgeon at the Childrens Hospital, which he had held for six years

Dr Post enjoyed clinical teaching and his service at the Dispensary gave him a large and varied amount of material for his demonstrations of syphilis There are doubtless many who now remember his twelve o'clock clinic in the old building at the Dispensary He always cautioned against overlooking extragenital non venereal infections of syphilis, and emphasized the importance of early recognition of such conditions

He was greatly interested in children with congenital syphilis This led him to study and record syphilitic families at a time when many doctors were simply treating the individual patient, without attempting to ascertain whether other members of the family had become infected

Dr Post was one of the first to make use of the x ray in studying syphilis of bones, joints and lungs He was an early advocate of the use of arsphenamine in the treatment of pregnant syphilitic women and their offspring

His interest in the early diagnosis and treatment of interstitial keratitis and symmetrical synovitis did much to conserve the eyesight and improve the health of these unfortunate children.

Dr Post began teaching in the Harvard Medical School in 1882 and continued until 1916, when he resigned as Professor of Syphilis and became an

MORBIDITY REPORT OF VENEREAL DISEASES

TREASURY DEPARTMENT, PUBLIC HEALTH SERVICE,
WASHINGTON

June 12, 1934

Managing Editor, *New England Journal of Medicine*,

Your attention is invited to the accompanying morbidity report of the venereal diseases for the month of April, 1934. This statement is prepared monthly by the Public Health Service and, because of the widespread prevalence of the venereal diseases, is of much importance to physicians and other individuals interested in the prevention and eradication of syphilis and gonorrhea. It is possible that you may find this statement of sufficient significance to publish it in your *Journal* regularly. A copy will be mailed to you in the future each month.

It is hoped that by releasing this statement, the Public Health Service may assist the State and local boards of health in interesting the individual physicians of the United States in the more thorough reporting of the venereal diseases. The present trend is to neglect the submission of such morbidity reports, yet the extensiveness of venereal disease prevalence can never be ascertained without the thorough cooperation and assistance of all of the physicians of the country. It is hoped that the publication of the morbidity reports by States may stimulate a spirit of friendly rivalry among physicians and health officers responsible for this activity.

Respectfully,

H. S. CUMMINGS, *Surgeon General*

The appended report presents the statistical evidence

HEALTH OFFICERS' MONTHLY STATEMENT OF
VENEREAL DISEASES REPORTED

April, 1934

This statement is issued monthly for the information of health officers in order to furnish current data as to the prevalence of the venereal diseases. The following reports were received from State Health Officers. The figures are preliminary and subject to correction. It is hoped that this will stimulate more complete reporting of these diseases.

State	Syphilis		Gonorrhea	
	Cases reported during month	Monthly case rates per 10,000 population	Cases reported during month	Monthly case rates per 10,000 population

BOOK REVIEWS

Aids to Pathological Technique By David H Haler
Students Aids Series 167 pp Baltimore William Wood and Company \$1.50

This small handbook of laboratory methods is concise in fact almost too concise to be of real service. For a quick review of laboratory subjects it has advantages. The methods recommended are somewhat different from those in common use in some of the laboratories in this country. In general it has more of the character of a sketchy quiz-compend than an adequate presentation of the subject and is certainly not to be recommended for the practitioner or laboratory worker.

Physiopathologie des Syndromes Endocriniens By Noël Flessinger 312 pp Paris Masson et Cie 40 fr

The reviewer read this book several months ago and put it aside to reread because he thought he was in a bad humor. As a result the review is late.

This book is an interesting attempt to approach clinical medicine from the physiological aspect. This excellent approach however is injured by loose statements both in regard to the laboratory work and the clinic. One reads an interesting account of disease and then one comes upon a statement which is obviously questionable. The names of authors are frequently referred to but there are no references given in the book so that there is the aspect of authority but yet no way of confirming statements by original evidence. From the re-

viewer's point of view this is a great handicap. The book has the excellent French characteristic of good clinical descriptions.

Synopsis of Obstetrics and Gynecology By Aleck W Bourne Fifth Edition 439 pp Baltimore William Wood and Company \$5.25

This book is fashioned after the manner of the quiz compends that have been published in this country for some years. For a hurried review of the subject it may be satisfactory but for any real student of obstetrics and gynecology this book is of no avail. It contains many statements with which American obstetricians do not agree, and much of the technique is not that which we follow in this country.

Aids to Qualitative Inorganic Analysis By R G Austin Students Aids Series 204 pp Baltimore William Wood and Company \$1.50

This miniature laboratory guide is apparently serviceable for the student of elementary chemistry. It is accurate so far as it goes, and may be useful for some one attempting to review chemistry for a basic science examination.

You Must Relax A Practical Method of Reducing the Strains of Modern Living By Edmund Jacobson. 201 pp New York and London Whittlesey House, McGraw Hill Book Company \$1.50

Some years ago this author wrote a more formal book on 'Progressive Relaxation' which contained much of value in regard to the physiology of the neuromuscular mechanism. He has now attempted, with much less success to write a small popular treatise on the same condition with the implication that muscular relaxation is a valuable adjunct to our therapy for conditions such as insomnia, colitis and hypertension. While much of the theory behind this little book is correct, one feels that its value is likely to be over-emphasized by the average reader. We talk about the strain of modern living but do we actually know how much this has to do with the psychoneuroses and hypertension? Is not the author basing his conclusions in regard to relaxation as a practical method of reducing neuromuscular tension on somewhat uncertain premises?

The Single Woman A Medical Study in Sex Education By Robert Latou Dickinson and Lura Beam 469 pp Baltimore The William & Wilkins Company

This book is the second volume of a series of case studies of which the first was entitled 'A Thousand Marriages'. With its avowed purpose—an inquiry into the sex life of the single woman

in the interests of sex education particularly with a view to marriage—your reviewer is in hearty accord. Whether this particular volume has accomplished its purpose and justified its publication is

Emeritus At the time of his death, he was the oldest member of the Harvard Faculty

In 1882 he was appointed on the Surgical Staff of the Boston City Hospital and rose to the rank of Senior Visiting Surgeon in 1897, resigning in 1906. As a surgeon he was resourceful, skillful and conservative. The good of the patient was always his objective. If unusual conditions demanded original procedures, his courage was never lacking. He performed oesophagotomy on a child for the removal of a silver twenty-five cent piece. The operation was successful.

In 1884, while Surgeon to Out Patients, Dr Post performed the first successful "bloodless operation" for the congenital dislocation of the hip joint. The patient was a girl of seven years. Recovery was complete, after wearing a plaster of Paris cast for about seven months, and the patient walked without a limp. It was nearly twenty years later that so much publicity was given Professor Lorenz of Vienna, when he carried out the same procedure on a little girl in New York City.

Dr Post took great interest in the training and welfare of his internes. He was at his best in teaching small groups. In 1894 he began the Thursday evening clinical meetings, held monthly for the Staff and former internes. This was one of the earliest, if not the beginning of such hospital meetings. For several years he gracefully presided at these carefully arranged and well-attended exercises. In 1907 he was appointed honorary consulting surgeon, which position he held at the time of his death.

He was appointed Consulting Physician in Syphilis at the Massachusetts General Hospital and for two years continued to teach Harvard Medical students in the newly created department for the care of all forms of syphilis. In this clinic, he and the late Dr George S. Derby studied the effect of arsphenamine treatment of interstitial keratitis as measured by vision tests. Dr Derby reported the results and conclusions on this group of cases in an article published in the *Ophthalmic Record* in 1917.

Dr Post was an Associate Editor of the *Boston Medical and Surgical Journal* from 1881 to 1890. His principal contributions to medical literature were in the fields of Surgery and Syphilology. His papers were carefully prepared, concise and convincing. He felt very strongly that from a medical standpoint syphilis should be looked upon as a chronic contagious disease rather than as a sex problem or social disease and should be treated as such.

As a public health measure he endeavored to locate, if possible, the source of infection and subsequent contacts and bring them under treatment. He was one of the first to appreciate the value of a social service worker in the clinic.

Dr Post's Clubs were the St. Botolph Yale Harvard and the Old University Club.

His membership in medical societies included the American Dermatological Association (of which he was one time president), American Medical Association, American Urological Association, Massachu-

setts Medical Society, New England Dermatological Society and other local medical societies.

He was a lover of nature, of flowers and of animals and for many years spent long seasons at his farm in Weston, Massachusetts. When he retired from practice he made his winter home in Cambridge. In spite of physical infirmities, incident to age, he retained his mental vigor enabling him to enjoy his family, his friends and his books until within a short time of his death.

RECENT DEATHS

DROWN—Miss LUCY LINCOLN DROWN, who served the Boston City Hospital first as a nurse, and later as Superintendent of Nurses for more than twenty-five years, died in Lowell, Massachusetts, June 22, 1934.

She retired in 1910 and will be long remembered as an important factor in the development of the training school for nurses at the City Hospital.

HEALY—DANIEL LAURENCE HEALY, M.D. of Framingham, Massachusetts, died at his home June 21, 1934.

He was born in Somerville in 1872, was educated at Boston College and graduated in medicine from the Harvard University Medical School in 1898, and had practiced in Framingham since that date. He had served as school physician. He joined the Massachusetts Medical Society in 1901, and served on the staffs of the Framingham and Natick Hospitals.

He is survived by his widow, Katherine G. Healy, two sons, Daniel J. and James Healy, five brothers, and five sisters.

LYMAN—HENRY LYMAN, M.D., a retired physician, died in Ponkapoag June 15, 1934. He was born in 1879, and graduated from the Harvard Medical School in 1912. He joined the Massachusetts Medical Society in 1914.

He was interested in farming and was a member of many social clubs. He is survived by his widow, Elizabeth (Cabot) Lyman and three children.

NOTICE

CORRECTION

In our issue of June 14, page 1298, there appeared an item stating that Dr. Moses Kaufmann had been elected to membership in the American Psychiatric Association at the meeting held in New York City in May 1934. The item should have read that Dr. Kaufman had been elected to Fellowship since he has been a member for five years.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

July 24-31—The IVth International Congress of Radiology will be held in Zurich under the presidency of Professor H. R. Schnitz. General Secretary Dr. H. E. Walther, Gloriastrasse 14, Zurich.

open to considerable question. The general impression gained is of a mass of poorly digested and badly correlated data. This could perhaps be condoned were we satisfied that the case histories represent a fair cross section of the emotional life and experiences of normal unmarried women. It would seem, however, to be a foregone certainty that case histories from the practice of one man will not be able to fulfill these requirements. In spite of these evident shortcomings the whole could have been saved from seeming futility by some thread of critical interpretation. The question we ask ourselves is why this has not at least been attempted. The book may still have something of interest for the student of abnormal psychology, but offers little of value for the average medical man.

Wilhelm Conrad Röntgen and the Early History of the Roentgen Rays By Otto Glasser, with a chapter by Margret Boveri. 494 pp. Illinois: Charles C. Thomas. \$6.00

This book of 494 pages contains considerably more than its title implies. It is not only an excellent biography of the Great German Physicist, but is also a complete history of the early experience with roentgen rays. In this portion of the book are such interesting data as the first observation on the physiological effects of roentgen rays on the human skin, the early use of roentgen ray as a therapeutic agent and the development of the roentgen tube and intensifying screens.

There is a complete bibliography of books and pamphlets on roentgen ray published during the year 1896, and when one considers that Roentgen announced his discovery in December, 1895, one is rather amazed to find that there were 49 books or pamphlets and over 1000 articles published the following year. In this list of articles are nearly all of the subjects under discussion to-day.

The book contains a vast amount of historical data related to the roentgen ray. In establishing these facts the author has exhausted every source of information and has included the references to these data in the bibliography. The book is easy to read and well printed.

As a book of reference it should be particularly valuable to those who wish to determine priority in any therapeutic or diagnostic procedure relating to the roentgen ray.

Traité de Physiologie Normale et Pathologique
Tome V. Respiration. Publié sous la direction du
Pr G. H. Roger et du Pr Léon Binet. 474 pp.
Paris: Masson et Cie. 80 fr.

Other volumes of this work have previously been reviewed in these columns. It may be recalled that the project is to publish the data of the science in great detail and to resume the collection of material as soon as each section is issued looking toward a new edition. With more than a hundred collaborators eleven large volumes have now been published and two of these are soon to be replaced

by revisions. The present unit appears to maintain the high standard set in its predecessors. Naturally, a large proportion of the references are to French sources, this is really a strong point for the book since these are the papers among which we are most apt to miss valuable reports. The chapter by Heymans on the nervous control of breathing will be of unusual importance because of the author's far-reaching discoveries with respect to the carotid sinus. Mention may also be made of the interesting treatment of basal metabolism by Hermann and of respiration at high altitudes by Binet.

Studies from The Rockefeller Institute for Medical Research Reprints Volume 88. 621 pp. New York: The Rockefeller Institute for Medical Research, 1934.

A very wide range of subjects is presented, covering the various departments of the Institute. From the medical standpoint the papers of particular interest are those by Rhoads and Castle on the pathology of the bone marrow in sprue, on focal cell reactions in tuberculosis by Theobald Smith, and infectious papillomatosis of rabbits by R. E. Shope.

From the standpoint of the laboratory worker, the three papers by H. M. Evans dealing with prolan are of particular interest.

Birth Control in Practice Text and Tables by Marie E. Kopp. Prepared under the supervision of a scientific advisory committee. 290 pp. New York: Robert M. McBride & Company. \$3.75.

"Birth Control in Practice" is a statistical study of the first ten years' work of the Birth Control Clinical Research Bureau of New York comprising the facts obtained from an analysis of ten thousand case histories. Some idea of the scope of this study can be gained from a glance at the Table of Contents. Statistics are presented concerning patients' reasons for seeking birth control advice, their nativity and national background, education, religious affiliations, occupations, weekly income, health, age and characteristics of husband, menstrual history, marital and obstetric history, including sexual habits and reactions, reasons for being given contraceptive advice, and other factors involved in the problem. The important findings are given in a brief summary of nine pages, by reading this carefully, one will get the gist of the study.

The book is a valuable contribution to our understanding of the problems of marriage and the sexual life. As Adolf Meyer, who wrote the foreword, very wisely remarks: "To bring sex life in its positive and not only its dismal aspects into contact with safe and sane and intelligent medical experience will be a tremendous forward step beyond the haphazard and often tragic conditions of the present day." "Birth Control in Practice" will help give us a foundation of knowledge upon which we may base the treatment of those patients whose problems are related to this important phase of life.

Drug Addic-
tion"

This institution has specialized in addictions for over 30 years. Its method of treatment has been fully described in THE JOURNAL A. M. A., in The Handbook of Therapy, from the A. M. A. Press, and in other scientific literature. The treatment is a regular hospital procedure, and provides a definite means for eliminating the toxic products of alcohol and drugs from the tissues. A complete Department of Physical Therapy, with gymnasium and other facilities for physical rebuilding, is maintained. Operated as an "open" institution. Physicians are not only invited but urged to accompany and stay with their patients.

STAMFORD HALL
 Stamford, Conn

ESTABLISHED 1891—TELEPHONE 3 1191

The largest private sanitarium in New England for the scientific treatment of nervous and mental diseases, drug and alcoholic addictions and general invalidism. Completely equipped for the care and comfort of patients. Thermo electric and hydrotherapeutic methods employed. Massage, occupational therapy and amusements. Located in a beautiful natural park of over one hundred acres with many detached cottages insuring privacy.

Excellent highways from any point in New England as well as frequent train service from all points on the New Haven Railroad.

Address

FRANK W. ROBERTSON, M.D.
Medical Director

WOODSIDE COTTAGES

Framingham, Massachusetts

A private sanitarium emphasizing normal homelike surroundings. Especially adapted to the care of chronic, convalescent and rest cases, at moderate rates. Committed cases not received.

Established in 1900

F. C. SOUTHWORTH, M.D. *Superintendent*
 FRANK W. PATCH, M.D. *Founder*

REEVES SANATORIUM

Melrose Highlands, Mass.

A large private house for non mental or mental cases not noisy or violent. It is licensed by the State and has resident physician and nurses.

F. B. Jewett, M.D. *Supt.*

Formerly Superintendent at the Rhode Island Hospital for Mental Diseases
 Tel. Melrose 0133

NURSING HOME

A pleasant home for convalescent in valids and elderly people. Large sunny rooms, piazzas and attractive grounds in a quiet neighborhood. Resident physician's services optional.

LUCIA F. VICKERY, M.D.

37 Greenough Ave.,
 Jamaica Plain, Mass
 Tel. Jam. 0072

B672-29 tf

O. R. T. L'ESPERANCE, M.D.
Hours 1 to 8

100 Boylston St. Boston—Tel. Hancock
 Genito-Urinary Diseases
 Specialty Gonorrhea

Perkins School of

Lancaster, Mass

Scientific Understanding and
 Education of Children of
 Retarded Development

Unsurpassed Home and School
 Equipment on 72 Acre Estate

Medical Direction Experienced Staff

FRANKLIN H. PERKINS, M.D.

GLENSIDE

Jamaica Plain, Boston, Mass

A small attractively located
 sanitarium for nervous mild
 mental or chronic illnesses

MABEL D. ORDWAY, M.D.
 6 Parley Vale Tel. Jamaica 44

BERKELEY
Preparatory School

Prepares for college entrance by
 certificate or examination. Small
 classes with individual attention.

Maternity Supports

Belts and corsets for pre- and post-natal wear, designed by Pomeroy to support the figure adequately and firmly, are made without useless extra straps and buckles. They are extremely comfortable and only the best materials and workmanship are used.

Made in several designs, two of which are shown

Left—Maternity Belt of Pink Satteen

Right—Maternity Corset with Elastic Front

Surgical Appliances Only Since 1867

*Definite dosage
Ease of administration
Sensible economy*

Each pill contains 0.1 gram (1½ grains) of physiologically tested digitalis leaves. The finished pills, too, are biologically assayed, thus giving re-assurance of their activity.

Each pill represents 15 minims of the U.S.P. tincture and permits of more accurate dosage than do liquids, as drops may vary in size.

These pills contain digitalis in its completeness and not any separated or extracted part of it, therefore present the entire therapy of this valuable drug.

Physician's trial size package and literature sent free upon request

DAVIES, ROSE & CO., Ltd
Pharmaceutical Manufacturers Boston, Mass

D8

When free samples are offered send for them. Even if you do not use them you may want to know what they are like.
